## PREFACE.

THis text-book is intended for use in scientific schools and colleges, in connection with courses in analytical chemistry, and aims to give a logical treatment of the calculations required of an analyst. As analytical chemistry is so closely allied with the other branches of chemistry, many of the calculations given will be found of general application. The matter has been selected so as not to encroach on the domain of physical chemistry but is intended to lead up to the study of that subject.

The object has been to furnish a text-book, which shall give the necessary information concerning those important chemical calculations, which every student should thoroughly understand before taking up advanced work. The method of presentation and arrangement differs materially from the old books on chemical calculations. Formulæ have been avoided, except in the last chapters, so that the student shall consider each problem individually and solve it from a knowledge of chemical laws instead of substituting in formulæ for different cases. If the student has in this way obtained ability to apply the laws, he can readily construct a formula or table for constand use.

More than two hundred examples are given, with answers ; all of which can be solved by arithmetic or algebra. They have been made as practical as possible in order to connect chemical laws with practical work. Numerous tables, which
have been carefully verified, will be found at the back of the book.

The assistance of Prof. Freedman of the University of Vermont on Chapter X. and of Dr. Joüet in correcting proof and verifying examples is gratefully acknowledged. Any corrections or suggestions will be much appreciated.

E. H. M.

Havemeyer Hall, Fanuary, 1900.

## PREFACE TO THIRD EDITION.

As a new edition of this book has become necessary, the opportunity is taken to make a thorough revision and enlargement. Experience with this text-book during the past four years has shown it to be advisable to subdivide the chapter on normal solutions and to make the explanations more full. The international atomic weights for 1904 have been introduced throughout the book and many new examples added.

The author acknowledges a number of corrections and helpful suggestions and the assistance of Mr. F. V. D. Cruser in recalculating the examples and in correcting the proof.
E. H. M.

Havemeyer Hall, September, 1904.

## TABLE OF CONTENTS.

CHAPTER I.Calculation of Chemical Equivalents and Atomic Weights.
Determination of Equivalents
PAGE.
Two Equivalents of Copper ..... 4I
Electrolytic Determination of Equivalents ..... 4
Definition of Atomic Weight ..... 5
Relation of Chemical Equivalents to Atomic Weights
Examples. ..... 9
CHAPTER II.
Calculation of Formule and Percentage.
Empirical Formula from percentage ..... 14
Formulæ of Minerals ..... 15
Oxygen Ratio ..... 18
Percentage Composition from Formula ..... 19
Percentage to the Dry Basis ..... 19
Examples ..... 23
CHAPTER III.
Calculations of Mixtures Having A Common Constituent.
Chlorine and Bromine in Mixed Silver Salts ..... 26
Sodium and Potassium in Mixed Sulphates ..... 28
Bicarbonate and Carbonate in Commercial Bicarbonate ..... 29
Formation of Mixtures of Definite Composition ..... 31
Examples ..... 33
CHAPTER IV.
Calculations from Equations.
Quantitative Meaning of Equations ..... 36
Weight of a Constituent in a Given Weight of a Compound ..... 37
Weight of a Constituent not in the Substance Weighed ..... 39
Quantity of Reagent Necessary to Complete a Reaction ..... 40
Choice of Most Economical Reagent ..... 42
Examples ..... 43

## CHAPTER I.

CALCULATION OF CHEMICAL EQUIVALENTS AND ATOMIC WEIGHTS.

## CHEMICAL EQUIVALENTS.

The calculations of analytical chemistry are based on the constant relations existing between the different elements in a chemical compound. These relations are best expressed by equivalents, that is, the weight of the element equivalent to one part of hydrogen. They are the equivalent quantities which will enter into reaction with one part by weight of hydrogen.

For example, if we decompose water by an electric current, we have hydrogen and oxygen given off and for every gram of hydrogen we find eight grams of oxygen, therefore the equivalent of oxygen is eight, for eight parts by weight of oxygen combine with one part by weight of hydrogen to give nine parts of water.

The equivalent of copper may be obtained as follows: When pure black oxide of copper is heated in a stream of hydrogen, the oxide is reduced to metallic copper and the oxygen combines with the hydrogen to form water, which can be absorbed by a weighed calcium chloride tube and reweighed after the experiment.

Suppose we take four grams of black oxide of copper and carry on the experiment until no more water is formed: then weigh; the metallic copper remaining is
3.196 grams : the loss in weight is the oxygen which was combined with the copper; so, as we know the equivalent of oxygen to be 8 , if we make the proportion 3.196 (the weight of copper): 0.804 (the weightof oxygen) : : $x: 8$, x will be the equivalent of copper, 3 I.8. Or weigh the water formed (the increased weight of the calcium chloride tube): this is 0.9045 gram. From this we can obtain a direct comparison between hydrogen and copper ; for, of the 0.9045 gram of water, 0.8040 gram is the oxygen lost by the copper oxide, so $0.9045^{-0.8040}$ or 0.1005 gram is the weight of hydrogen which has combined with the oxygen previously in combination with copper; hence $\frac{3.196}{0.1005}$ or 3 I .8 is the weight of copper equivalent to one gram of hydrogen or the chemical equivalent of copper.

To obtain the equivalent of bismuth, the metal can be treated with nitric acid until it is completely converted to oxide and after ignition weighed.* 3.6770 grams of bismuth gave 4 .IOI 6 grams of oxide. The increased weight 0.4246 gram is the oxygen combined with 3.6770 grams of bismuth, hence the equivalent of bismuth will be found from the proportion

$$
36770: 0.4246:: x: 8 . x=69.27
$$

If we heat finely divided bismuth with an excess of sulphur and add small portions of sulphur until the bismuth is completely converted to sulphide, then remove the excess of sulphur by digesting with a caustic alkali solution, we can from the increased weight find the equivalent of sulphur. For example, 3 grams of bismuth gave 3.6928 grams of sulphide. To get the equivalent of sulphur. $3: 0.6928:: 69.27: x . \quad x=16$.

[^0]We have now the following equivalents: Oxygen, 8 ; Copper, 3 1.8; Bismuth, 69.27 ; Sulphur, 16 . To obtain that of silver, heat together pure finely divided silver and an excess of sulphur, volatilize the excess of sulphur and weigh the resulting silver sulphide. Suppose these to be the results : 4 grams of silver gave 4.592 grams of sulphide; then $0.592: 4:: 16: x . x=108$, the equivalent of silver. Now that we have obtained the equivalent of silver, we can combine it with a number of elements and get their equivalents. For example, dissolve three grams of silver in nitric acid and pass in chlorine until the silver is completely precipitated or pass chlorine over the silver heated in a combustion tube until it is completely converted into chloride: weigh the silver chloride; weight, 3.986 r grams. To calculate the equivalent of chlorine we have $0.986 \mathrm{I}: 3: \mathrm{x}:$ ro8. $\mathrm{x}=35.5$. In a similar way the equivalents of bromine and iodine can be found.

This process of obtaining one equivalent from another can be carried on indefinitely until those of all the known elements have been determined, but each successive comparison involves an increase of error so that whenever possible these indirect results are confirmed by a direct comparison with hydrogen or oxygen. In the course of such a set of determinations, it frequently occurs that two or more entirely different equivalents are obtained for the same element.

This shows that the element may combine in different proportions and as the different equivalents are invariably multiples of the lowest, it proves that the elements combine in simple and definite proportions represented by whole numbers.

To illustrate this: suppose in the experiment described with black oxide of copper, we substitute red
oxide-4 grams as before, and weigh the copper remain-ing- 3.553 grams. We shall have to obtain the equivalent of copper

$$
3.553: 0.447:: x: 8 . \quad x=63.6
$$

which is exactly double that obtained from the black oxide, so that 8 parts by weight of oxygen combine in one case with 3 I. 8 parts of copper and in the other with 63.6 parts. This leads to the conclusion that the red oxide contains exactly one half as much oxygen as the black oxide in proportion to copper. When we attempt to construct formulae from these results, we are confronted by a difficulty, for $\mathrm{Cu}_{2} \mathrm{O}$ and CuO or CuO and $\mathrm{CuO}_{2}$ equally well represent the proportions of oxygen to copper found. To distinguish between these, both molecular weight determinations and study of the salts corresponding to the respective oxides and the analogous compounds of similar elements, are necessary.

Equivalents may also be determined electrolytically, for according to Faraday's Law, the same quantity of electricity precipitates or liberates chemically equivalent quantities of all elements. Suppose we connect in series, cells containing suitable solutions of cuprous copper, cupric copper and of silver respectively, each provided with platinum electrodes; then pass a weak current through the three, as they are connected in series they obtain the same current; so that the weights of metal precipitated are proportional to the chemical equivalents. Suppose the weights precipitated are silver 0.756 gram ; copper, 0.4452 in one case, and 0.2226 in the other. If we know one equivalent we can find the others; if we know that of silver to be 108, to find the two equivalents of copper we have

$$
\begin{gathered}
0.756: 0.4452:: 108: x . \quad x=63.6 . \\
0.756: 0.2226:: 108: y . \quad y=31.8 .
\end{gathered}
$$

For the relations between chemical and electrochemical equivalents see Chapter X.

## ATOMIC WEIGHTS.

The atomic weight of an element is the weight of an atom compared with the weight of an atom of hydrogen taken as unity or an atom of oxygen taken as sixteen. This latter definition is very generally adopted, for the ratio of oxygen to hydrogen has been found by most careful experiments to be not 16 to I but 15.88 to i and, as the value for oxygen enters into a great number of atomic weight calculations, it is more convenient to take it as a whole number, 16 , and make it the base of the system. If we use $O=16$, hydrogen then becomes I. 008 when great exactness is required.

The atomic weight is equal to, or a multiple of, the equivalent, for an element can combine with one or more hydrogen atoms or some other element in different proportions depending on its valence, and while this affects its equivalent it does not its atomic weight which is an invariable property of the element. To determine which multiple of the equivalent is the atomic weight is sometimes a matter of difficulty; which requires a knowledge of the laws and methods of physical chemistry for its certain solution, particularly those regarding molecular weights, which are not within the province of this book. If, however, we take the least common multiple of the equivalents, when the element has several, we get a number which satisfies all analytical data and is the atomic weight subject to confirmation by physical data and the periodic law.

In order not to leave the question of atomic weights in such a vague condition, let us assume the correctness
of the following facts, for the proof of which the student is referred to books on physical chemistry.
I. That the product of the specific heat of an element in the solid state and the atomic weight is a constant (approximately) 6.4. Law of Dulong and Petit.
2. That equal volumes of all gases under the same temperature and pressure contain the same number of molecules. Law of Avogadro.
3. That the gaseous molecules of all elements consist of two atoms, except potassium, sodium, zinc, cadmium, and mercury which are monatomic, phosphorus and arsenic which are tetratomic and sulphur which is variable according to temperature. (Phosphorus, arsenic and sulphur are diatomic however at very high temperatures).

With the aid of these laws we can readily confirm our provisional atomic weights as follows:-The least common multiple of our equivalents for copper, 31.8 and 63.6 , is 63.6 ; the specific heat of copper is 0.095 (see table) $63.6 \times 0.095=6.042$; a result which approximates 6.4 with sufficient closeness to show any other multiple of the equivalent to be incorrect. Again we found the equivalent of silver to be 108 ; its specific heat is 0.057 and the product is 6.15 , a result which shows that the atomic weight and equivalent of silver are identical.

This principle can be applied to all elements whose specific heats in the solid state are accurately known, but will not aid us to confirm the atomic weight of many of the non-metallic elements. To do this we must consider the other facts. Take a diatomic molecule such as chlorine and compare the weight of a liter of this with the weight of a liter of hydrogen, at the same temperature and pressure. According to the law of Avogadro these volumes contain the same number of
molecules. Let $x=$ number of molecules in a liter, then weight x chlorine molecules: weight x hydrogen molecules: : weight one chlorine molecule: weight one hydrogen molecule. And as one chlorine molecule and one hydrogen molecule each contain two atoms, we have, weight liter of chlorine: weight liter of hydrogen:: atomic weight of chlorine: atomic weight of hydrogen: or $3.1673: 0.0896:: x: 1 . x=35 \cdot 35 \cdot$ A result which confirms with sufficient accuracy our equivalent 35.5 as the atomic weight of chlorine,

To determine the atomic weight of mercury.

1. Ignite 5 grams of mercuric oxide and weigh the resulting mercury- 4.62 grams. The loss in weight 0.38 gram is oxygen and the equivalent of oxygen is 8 so $0.38: 4.62:: 8: x . \quad x=97.26$. The equivalent of mercury.
2. Dissolve 5 grams of corrosive sublimate in water, acidify with nitric acid and precipitate the chlorine in combination by silver nitrate. Weigh the silver chloride, $5.295^{2}$ grams. We have found the equivalents of chlorine and silver to be 35.5 and 108, therefore to get the chlorine in this precipitate we have

$$
108+35.5: 35 \cdot 5:: 5.295^{2}: x . \quad x=1.3099 \text { grams, }
$$

the amount of chlorine combined originally with the mercury ; 5-1.3099 $=3.690$ r, the amount of mercury present in the five grams of mercuric chloride. So to get the equivalent of mercury we have,

$$
3.6901: 1.3099:: x: 35 \cdot 5 . \quad x=100 .+
$$

3. Fuse 5 grams of calomel with an excess of alkaline carbonate in a porcelain crucible, leach out the alkaline chloride formed and precipitate it with an excess of silver nitrate ; weigh the silver chloride, 3.0466 grams.

Calculate the chlorine present as before

$$
143.5: 35.5:: 3.0466: x . \quad x=0.7537 \text { gram. }
$$

To calculate the equivalent of mercury we have

$$
\text { 5. }-0.7537: 0.7537:: x: 35 \cdot 5 . \quad x=200
$$

We have before us three equivalents of mercury, between the first and second, the indirect determination has the greater probability of accuracy on account of loss of mercury by heating, so the two reliable equivalents are 100 and 200 . Therefore the provisional atomic weight, the least common multiple, is 200 . This is easily confirmed by the specific heat: 0.0319 times $200=6.38$. So that 200 is the atomic weight of mercury and we can assign to the two chlorides formulae of HgCl and $\mathrm{HgCl}_{2}$ unless their molecular weights show them to be multiples.

## EXAMPLES.

For specific heat of metals see tables on page 180.
i. Five grams of pure zinc were treated with dilute hydrochloric acid and the hydrogen evolved was dried, measured and the corresponding weight calculated; this was 0.1529 gram. What is the equivalent and the atomic weight of zinc? Ans. 32.7 and 65.4.
2. One gram of pure metallic magnesium was burned in an atmosphere of oxygen and the resulting oxide collected and weighed. Weight 1.658 grams. What is the atomic weight of magnesium? Ans. 24.31.
3. a. Two grams of silver were dissolved in nitric acid and bromine water added until no more precipitate formed. Weight of silver bromide was 3.481 grams. Given the equivalent of silver, 108. What is the equivalent of bromine? Ans. 79.97.
b. Given the weight of a liter of bromine vapor, 7.1675 grams and the weight of a liter of hydrogen under the same conditions, 0.0896 gram. What is the atomic weight of bromine?

Ans. 79.99.
4. Three grams of silver are precipitated by an excess of iodine. Weight of silver iodide was 6.5277 grams.

Three grams of silver are precipitated by an excess of chlorine. Weight of silver chloride, 3.9861 grams.

Given the equivalent of chlorine, $35 \cdot 5$. What is the equivalent of iodine? Ans. 127.
5. Roscoe found that 6.4428 grams of Cape diamonds gave 23.6275 grams of carbon dioxide when burned in air.

Van der Plaats found that 30.889 i grams of sugar charcoal gave II 3.2320 grams of carbon dioxide. Given $\mathrm{O}=16$. What is the atomic weight of carbon ?

$$
\text { Ans. } 12 .
$$

6. Richards and Rogers found that 2.35079 grams of zinc bromide gave 3.91941 grams of silver bromide. Given $\mathrm{Br}=79.95$ and $\mathrm{Ag}=107.92$. What are the equivalent and atomic weights of zinc?

Ans. 32.73 and 65.46.
7. Winkler converted electrolytically deposited nickel to a dry chloride and then weighed the chlorine as silver chloride. He obtained from 0.301 I gram of nickel 1.4621 grams of silver chloride. Given $\mathrm{Ag}=$ 107.92 and $\mathrm{Cl}=35.37$. What are the equivalent and atomic weights of nickel? Ans. 29.5 and 59.
8. Deville found that 0.6763 gram of boron chloride, obtained by the action of gaseous hydrochloric acid on boron, gave 2.4770 grams of silver chloride. Given $\mathrm{Ag}=107.92$ and $\mathrm{Cl}=35.37$. What is the chemical equivalent of boron?

$$
\text { Ans. } 3.75 .
$$

9. Dumas found that it required 4.168 grams of silver (as nitrate) to precipitate the chlorine from 4.0162 grams of anhydrous barium chloride. Given the equivalents of silver and chlorine, 107.92 and 35.37 . What is the chemical equivalent of barium? Ans. 68.62.
10. Stas found that after adding 7.25682 grams of potassium chloride to 10.51995 grams of silver, dissolved in nitric acid, that o.o194 gram of silver remained in solution. Given the atomic weights of chlorine and silver as 35.37 and 107.92. Calculate that of potassium.

$$
\text { Ans. } \quad 39.2 .
$$

ir. Mallet determined the atomic weight of aluminium by the following methods:
(a) by oxidizing to water the hydrogen evolved when aluminium was dissolved by sodium hydroxide : 5.2632 grams of aluminium gave 5.2562 grams of water.
(b) by precipitating the bromine in aluminium bromide as silver bromide : 8.6492 grams of aluminium bromide required 10.4897 grams of silver.

Calculate the atomic weight of aluminium. Given $\mathrm{Ag}=107.92, \quad \mathrm{Br}=79.95, \quad \mathrm{O}=16, \mathrm{H}=1.008$. Ans. (a)27.06. (b)27.105.
12. If 5 grams of a metallic bromide gave 7.2552 grams of iodide, and the atomic weights of bromine and iodine are 79.95 and 126.85 respectively. What would be the atomic weight of the metal if it were univalent, bivalent or trivalent? Ans. 24, 48, 72 .
13. 1.4480 grams of calcite gave on ignition 0.8 II 6 gram of lime. Given the atomic weights of carbon and of oxygen as 12 and 16 . What is the chemical equivalent of calcium?

Ans. 20.057.
14. 2.6146 grams of metallic tin gave 3.3196 grams of oxide. Given the chemical equivalent of oxygen as 8 . What is the atomic weight of tin? Ans. 118.68.
15. 0.5302 gram of metallic antimony was mixed with sulphur in a porcelain boat and heated at $250^{\circ} \mathrm{C}$. in a current of carbon dioxide until the excess of sulphur was sublimed. The resulting sulphide weighed 0.7429 gram. Given the equivalent of sulphur, 16 . What is the atomic weight of antimony? Ans. II9.64.
16. O.I 700 gram of zinc gave on treatment with acid 58.23 c.c. of hydrogen gas. Given the weight of a litre of hydrogen, 0.0896 gram. What is the atomic weight of zinc?

Ans. 65.16.
17. If 0.0899 gram of aluminium gave ilo.8 c.c. of hydrogen, what is the atomic weight of aluminium? Given the weight of a litre of hydrogen, 0.0896 gram.

$$
\text { Ans. } 27.15
$$

18. $0.55^{26}$ gram of metallic bismuth showed an increase in weight of 0.1278 gram on being completely converted to sulphide. Given the equivalent of sulphur 16. What is the atomic weight of bismuth ?

Ans. 207.54.
19. If 4 grams of an oxide gave 5 grams of a sulphide, and the atomic weights of oxygen and sulphur are 16 and 32 , what would be the atomic weight of the element, if it were univalent, bivalent or trivalent?

$$
\text { Ans. } 24,48 \text { and } 72 .
$$

20. Parsons found that 1.4793I grams of basic beryllium acetate, $\mathrm{Be}_{4} \mathrm{O}\left(\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right)_{6}$, gave 0.36534 gram of oxide, BeO . Calculate the atomic weight of Be . Given $\mathrm{C}=\mathrm{I} 2, \mathrm{O}=16, \mathrm{H}=\mathrm{I} .008$. Ans. 9.101.
21. Scott found that 4.84099 grams of ammonium bromide $\left(\mathrm{NH}_{4} \mathrm{Br}\right)$, when precipitated by silver nitrate, gave 5.33177 grams of silver Given $\mathrm{H}=1.008, \mathrm{Br}$ $=79.96, \mathrm{Ag}=107.93$. What is the atomic weight of nitrogen?

Ans. 14.00 .
22. 1.05462 grams of silver arsenate $\left(\mathrm{Ag}_{3} \mathrm{AsO}_{4}\right)$ were converted into silver chloride by passing a current of hydrogen chloride gas over the substance in a porcelain boat, 0.98014 gram of silver chloride was obtained.* Given $\mathrm{Ag}=107.93, \quad \mathrm{O}=\mathrm{I} 6, \quad \mathrm{Cl}=35.45$. What is the atomic weight of arsenic? Ans. 75.04.
23. Richards and Merigold found that from 1.7999 grams of uranium bromide $\left(\mathrm{UrBr}_{4}\right)$, when converted to $\mathrm{AgBr}, \mathrm{I} .3918$ grams of silver were obtained. What is

* Ebaugh, J. Am. C. S., 24, 493.
the atomic weight of uranium? Given $\mathrm{Ag}=107.93$, $\mathrm{Br}=79.96$.

Ans. 238.47 .
24. Lenher found that 0.98396 gram of pure silver selenite $\left(\mathrm{Ag}_{2} \mathrm{SeO}_{3}\right)$, yielded 0.82232 gram of silver chloride, when treated in a current of hydrochloric acid gas to expel the selenium and oxygen. Given $\mathrm{Ag}=$ 107.93, $\mathrm{O}=16, \mathrm{Cl}=35.45$. What is the atomic weight of selenium? Ans. 79.27.
25. Taylor heated 0.485 I 4 gram of metallic tungsten in a current of oxygen until all the metal was converted to oxide, which weighed 0.6I i 66 gram. Given the chemical equivalent of oxygen as 8 . What is the atomic weight of tungsten? Ans. 184.06.

After this introduction on the determination of atomic weights, the student should have a definite idea of their meaning and how they can be obtained. In the calculations and examples from this point the atomic weights given on page 177 will be used unless especially mentioned. These were adopted by the International Committee on atomic weights for 1904.

## CHAPTER II.

## CALCULATION OF FORMULAE AND PERCENTAGE.

## FORMULA FROM PERCENTAGE.

In any chemical compound, if we divide the percentages obtained from analysis by the atomic weights of the elements, we shall get numbers which represent the ratio of atoms, and on reducing these to the nearest whole numbers, obtain the empirical formula-the simplest ratio of atoms. The correct formula may however be a multiple of this which would have the same percentage composition. Therefore a determination of the molecular weight is necessary to decide what multiple of the empirical formula is the correct one. For the methods and calculations used in determining molecular weights, except from the specific gravity of a gas, the reader is referred to the numerous text books on physical chemistry.

The empirical formula is usually obtained from an analysis, and while the proper multiple should be used in all equations, yet the empirical formula serves many useful purposes in inorganic analysis, such as furnishing data for normal solutions, factors, etc., just as correctly as the proper molecular formula.

In organic chemistry, this is not the case as the existence of many totally different bodies having the same empirical formula, makes it essential to use the molecu-
lar or better the graphic formulae. The following examples illustrate the calculation of empirical formulae:

A salt gave on analysis $52.45 \%$ of potassium and $47.55 \%$ of chlorine,

$$
\begin{aligned}
& 52.45 \div 39.15=\mathrm{I} .34 \mathrm{O} \\
& 47.55 \div 35.45=\mathrm{I} .34 \mathrm{I}
\end{aligned}
$$

the ratio of atoms is 1.341 to I .34I or I to I , so the formula has an equal number of atoms of potassium and chlorine and the empirical formula is KCl .

A salt gave on analysis the following:

| P |  | $2 \mathrm{I} .82 \% \div 3 \mathrm{I} .=0.704$ |  |
| :---: | :---: | :---: | :---: |
| Hydrogen |  | $0.710 \div 1.01=0.703$ |  |
| Sodium |  | $32.43 \% \div 23.05=1.407$ |  |
| xy |  | $=2$ |  |

If we divide the numbers representing the ratio of atoms by the greatest common-divisor 0.703 we get the ratio expressed in the nearest whole numbers, or phosphorus I; hydrogen I; sodium 2 ; oxygen 4 . The empirical formula is therefore $\mathrm{PHNa}_{2} \mathrm{O}_{4}$ or as it is usually written $\mathrm{Na}_{2} \mathrm{HPO}_{4}$.

Analysis of ignited magnesium ammonium phosphate gave the following results:
Magnesium $21.82 \% \div 24.36=0.8957 \div 0.449=2$.
Phosphorus $27.860 \% \div 31 . \quad=0.8987 \div 0.449=2$.
Oxygen $\quad 50.32 \% \div 16 .=3.145 \div 0.449=7$.
The greatest common divisor of the numbers representing the ratio of atoms is 0.449 : dividing by this we obtain the nearest whole numbers. So the empirical formula is $\mathrm{Mg}_{2} \mathrm{P}_{2} \mathrm{O}_{7}$.

## formulae of minerals.

From the results of analysis the formula of a mineral can be calculated as in the case of any other empirical formula; but as one element or group often replaces
another to a greater or less extent without altering the mineralogical character, those elements which may replace each other are grouped together and represented by the letter R . So oxides of the monatomic elements, such as the alkalies, are represented by $\mathrm{R}_{2} \mathrm{O}$; oxides of the diatomic elements, such as calcium, magnesium, barium, ferrous iron, manganese, etc., by RO; oxides of aluminium, chromium, ferric iron, manganic manganese, etc., by $\mathrm{R}_{2} \mathrm{O}_{3}$ and so on. In this way the composition of the mineral is indicated and especially the ratio of basic to acid oxides.

For example, analysis of Franklinite gave the following results:*

| $\mathrm{Fe}_{2} \mathrm{O}_{3}$ | 60.52 | 66.34 | $67 . \mathbf{n}^{2}$ |
| :--- | ---: | ---: | ---: |
| $\mathrm{Mn}_{2} \mathrm{O}_{3}$ | 6.79 | - |  |
| ZnO | 19.44 | 20.26 | 6.78 |
| MnO | 12.8 I | 12.31 | 9.53 |
| FeO | - | - | 15.65 |

We see in (I) a replacement of part of the $\mathrm{Fe}_{2} \mathrm{O}_{3}$ by $\mathrm{Mn}_{2} \mathrm{O}_{3}$; so that $\mathrm{R}_{2} \mathrm{O}_{3}$ in this case is ferric iron and manganic manganese, comparing (I), (2), and (3), we see that the percentages of $\mathrm{ZnO}, \mathrm{MnO}$ and FeO vary greatly, these constitute the RO group.

In (I) calculate from the percentage of $\mathrm{Mn}_{2} \mathrm{O}_{3}$ the equivalent percentage of $\mathrm{Fe}_{2} \mathrm{O}_{3}$. To do this we have, the percentage of $\mathrm{Mn}_{2} \mathrm{O}_{3}$ is to the percentage of $\mathrm{Fe}_{2} \mathrm{O}_{3}$ as the molecular weight of $\mathrm{Mn}_{2} \mathrm{O}_{3}$ is to the molecular weight of $\mathrm{Fe}_{2} \mathrm{O}_{3}$. The molecular weight of $\mathrm{Mn}_{2} \mathrm{O}_{3}$ is $(2 \times 55)+\dagger(3 \times 16)$ or 158 and that of $\mathrm{Fe}_{2} \mathrm{O}_{3}$ is (2 $\times 55.9)+(3 \times 16)$ or 159.8 . So the proportion becomes,

$$
6.79: x:: 158: \text { 159.8. } x=6.87 \%
$$

[^1]In the same way, using the proper molecular weights, calculate the percentage of MnO , to the equivalent per. centage of ZnO ,

$$
\text { I2.81 }: y:: 7 \mathrm{I} .: 8 \mathrm{I} .4 . \quad \mathrm{y}=14.68 \%
$$

We have now $\mathrm{Fe}_{2} \mathrm{O}_{3}, 60.52 \%+6.88 \%=67.40 \%$ and $\mathrm{ZnO}, 19.44 \%+14.68 \%=34.12 \%$. Dividing these bv the molecular weights we get

$$
\begin{aligned}
& 67.40 \% \div 159.8=0.422 \div 0.420=1 .+ \\
& 34.12 \% \div 81.4=0.419 \div 0.420=1 .-
\end{aligned}
$$

These results are almost identical, so the ratio of $\mathrm{R}_{2} \mathrm{O}_{3}$ to $R O$ is 1 to $I$ and the formula is represented by $\mathrm{RO}, \mathrm{R}_{2} \mathrm{O}_{3}$.

There was no particular reason for calculating the percentage of MnO to ZnO rather than ZnO to MnO ; the result when divided by the proper molecular weight will be the same in either case.

The typical formula can also be found by dividing the percentage of each oxide by its molecular weight and then grouping together the ratios as follows-
(2) $\mathrm{Fe}_{2} \mathrm{O}_{3} 66.34 \div \mathrm{I} 59.8=0.415$.

$$
\left.\begin{array}{ll}
\mathrm{ZnO} & 20.26 \div 81.4=0.249 \\
\mathrm{MnO} & 12.31 \div 71 .=0.172
\end{array}\right\}=0.421
$$

The ratio is approximately one to one as before. The lack of agreement in the figures representing the ratio is probably due to a deficiency in the percentage of $\mathrm{R}_{2} \mathrm{O}_{3}$ elements for the percentages only add up to 98.91.

From the third analysis we get $0.422: 0.436$, again showing the ratio to be one to one.

So from the results of these three analyses we find the formula of Franklinite to be $(\mathrm{Zn} \mathrm{Mn} \mathrm{Fe}) \mathrm{O},(\mathrm{Fe} \mathrm{Mn})_{2} \mathrm{O}_{3}$.

Dana's Mineralogy gives the following analyses of garnets,

|  | (1) | (2) |
| :--- | ---: | ---: |
| $\mathrm{SiO}_{2}$ | 40.90 | 39.85 |
| $\mathrm{Al}_{2} \mathrm{O}_{3}$ | 22.8 I | 22.07 |
| $\mathrm{Fe}_{2} \mathrm{O}_{3}$ | - | I 13 |
| $\mathrm{Cr}_{2} \mathrm{O}_{3}$ | I .48 | - |
| FeO | I 3.34 | - |
| MnO | 0.38 | - |
| MgO | 16.43 | 0.68 |
| CaO | 4.70 | 36.3 I |

The $\mathrm{R}_{2} \mathrm{O}_{3}$ bases are calculated to $\mathrm{Al}_{2} \mathrm{O}_{3}$ as the percentages of $\mathrm{Fe}_{2} \mathrm{O}_{3}$ and $\mathrm{Cr}_{2} \mathrm{O}_{3}$ are small and indicate a partial replacement of the $\mathrm{Al}_{2} \mathrm{O}_{3}$. With the RO bases we may calculate either to CaO or MgO and divide the sum of the resulting percentages by the molecular weight of the oxide we select. After calculating $\mathrm{Cr}_{2} \mathrm{O}_{3}$ and $\mathrm{Fe}_{2} \mathrm{O}_{3}$ to $\mathrm{Al}_{2} \mathrm{O}_{3}$ and $\mathrm{FeO}, \mathrm{MnO}$, and MgO to CaO we get
( I )
$\mathrm{SiO}_{2}$
$\mathrm{Al}_{2} \mathrm{O}_{3}\left(\mathrm{R}_{2} \mathrm{O}_{3}\right)$
$\mathrm{CaO}(\mathrm{RO})$

$$
40.90 \% \div 60.4=0.677
$$

$$
23.80 \% \div 102.2=0.236
$$

$$
38.25 \% \div 56.1=0.682
$$

(2)
$\mathrm{SiO}_{2}$
$\mathrm{Al}_{2} \mathrm{O}_{3}\left(\mathrm{R}_{2} \mathrm{O}_{3}\right)$

$$
22.79 \% \div 102.2=0.223
$$ CaO ( RO )

$$
39.85 \% \div 60.4=0.660
$$

$$
37.26 \% \div 56.1=0.664
$$

So in both cases the type formula is $3 \mathrm{RO}, \mathrm{R}_{2} \mathrm{O}_{3},{ }_{3} \mathrm{SiO}_{2}$.
In connection with silicates both natural and artificial (slags) the term "oxygen ratio" is often used. This means the ratio of the oxygen atoms belonging to the basic groups to those combined with silicon. In the garnet we have six oxygen atoms combined as basic oxides and six as an acid oxide $\left(\mathrm{SiO}_{2}\right)$, hence the oxygen
ratio is one to one, or if it is desired to distinguish between the basic oxides $1: 1: 2$. In writing these ratios the order adopted is first RO , then $\mathrm{R}_{2} \mathrm{O}_{3}$ and last $\mathrm{SiO}_{2}$.

## PERCENTAGE COMPOSITION FROM FORMULA.

If we have the formula of a compound whether molecular or empirical and the atomic weights of its elements the calculation of the percentage composition is made as follows.-Take for example sodium chloride; we have the formula NaCl and the atomic weights Na 23.05 and Cl 35.45 . The molecular weight is the sum of the atomic weights, $23.05+35.45=58.5$, the molecular weight of NaCl . Let $x=0 \mathrm{Na}$ and $\mathrm{y}=\% \mathrm{Cl}$ then

$$
\begin{array}{r}
23.05: 58.5:: x: \text { 100. } x=39.402 \% \\
35.45: 58.5:: y: \text { 100. } y=60.598 \% \\
\text { To prove } x+y=100.00 \%
\end{array}
$$

To calculate the percentage composition of ethyl alcohol, $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$. The molecular weight is $24.00+6.05$ $+16=46.05 . \quad$ Let $x=\% \mathrm{C}, \mathrm{y}=\% \mathrm{H}$ and $\mathrm{z}=\% \mathrm{O}$. 24. $: 46.05:: x: 100 . x=52.117 \%$ C. $6.05: 46.05:: y: 100 . y=13.138 \% \mathrm{H}$.
16. : $46.05:: z: 100 . z=34.745 \% \mathrm{O}$. To prove $x+y+z=100 \%$.
By similar proportions the percentage composition of any substance whose formula is known can be calculated.

CALCULATION OF PERCENTAGE TO THE DRY BASIS.
Ores and other material often contain moisture: it is frequently necessary to calculate what the percentage of a constituent would be if this water were removed and the reverse.

If an ore contains $10 \%$ of moisture and $42 \%$ of manganese, what will be the percentage of manganese on the dry basis? Let us represent the weight of the wet sample by 100 parts; then after drying we will have 100-10 (the parts of water): let $\mathrm{x}=$ the percentage of manganese on the dry basis; then, as no manganese is lost or gained by the removal of water, we have $42 \times 100=x$ (roo-10). $x=46.66 \%$ or, in general if we divide the percentage by 100 minus the percentage of moisture we get the percentage on the dry basis.

If an ore contains $58 \%$ of iron on the dry basis, what is the percentage of iron when $18 \%$ of water is present?

$$
58: x:: 100: 82 . \quad x=47.56
$$

for the original ore may be regarded as made up of 82 parts of dry ore containing $58 \%$ of iron and 18 parts of water containing no iron.

These examples are of very great importance as the quantity of moisture in a shipment of ore, coal, etc., may be quite different when it arrives at its destination from that which it contained when shipped. In order that the chemists for the buyer and seller may agree, their results must be calculated to a common basis, usually the dry basis.

If a carload of ore were sold as containing $42 \%$ of lead, and the buyer found $40 \%$ of lead, and $6 \%$ of water, what must have been the percentage of water in the original sample, provided both chemists were perfectly accurate?

The buyer's chemist found that 94 parts of dry ore contained 40 parts of lead. Let $\mathrm{x}=$ number of parts to contain 42 parts of lead; then

$$
40: 42:: 94: x . \quad x=98.70 .
$$

The original ore must have contained $\mathrm{I} .30 \%$ of water.

At times samples are received in a wet condition, and as the water will be constantly evaporating in the laboratory, the sample must be weighed, and air-dried at once.

A wet sample of coal weighed 800 grams; this was dried at a temperature of $60^{\circ} \mathrm{C}$. and lost $8 \%$ of water. The partially dried sample was analyzed and found to contain $2.5 \%$ of water. What was the percentage of water in the original sample?

The air-dried sample was made up of 97.5 parts of coal and 2.5 parts of water. The wet sample was made up of 92 parts of the partially dried sample and 8 parts of water.

To get the water in 92 parts of the partially dried sample, we have :

$$
100: 92:: 2.5: x . \quad x=2.30
$$

To get the total water in the wet sample $2.30+8$ $=10.30$.

Ans. $10.30 \%$.
Let us suppose that the analysis of the air-dried sample gave the following results: Moisture $2.50 \%$. Volatile combustible matter $18 \%$. Fixed carbon $65.50 \%$. Sulphur $2 \%$. Ash $12 \%$. What are the percentages on the dry basis?

$$
\begin{aligned}
18 \div 0.975 & =18.46 \% \\
65.5 \div 0.975 & =67.18 \% \\
2 \div 0.975 & =2.05 \% \\
12 \div 0.975 & =\frac{12.31 \%}{100} .
\end{aligned}
$$

What are the percentages in the original sample?

$$
\begin{aligned}
18 \times 0.92= & 16.56 \% \\
65 \times 0.92= & 60.26 \% \\
2 \times 0.92= & 1.84 \% \\
12 \times 0.92= & 11.04 \% \\
\text { Water } & \frac{10.30 \%}{100}
\end{aligned}
$$

These results can also be obtained by multiplying the weights in one gram on the dry basis by 100 minus the percentage of water ; in this case by 89.70 .

## EXAMPLES.

Calculate the empirical formulae from the following analytical results.
I. Lead $68.30 \%$. Sulphur $10.55 \%$. Oxygen by difference, 2 I. $15 \%$.
2. Arsenic 4 I. $32 \%$. Chlorine $58.66 \%$.

$$
\mathrm{Ans} . \mathrm{AsCl}_{3} .
$$

3. Potassium $35.56 \%$. Iron $17.00 \%$. Cyanogen by difference, $47.44 \%$. Ans. $\mathrm{K}_{3} \mathrm{Fe} \mathrm{C}_{6} \mathrm{~N}_{6}$.
4. Carbon $37.5 \%$. Hydrogen $12.5 \%$. Oxygen by difference, $50 . \%$. Ans. $\mathrm{CH}_{4} \mathrm{O}$.
5. Carbon $40.67 \%$. Hydrogen $8.47 \%$. Nitrogen $23.73 \%$. Oxygen by difference, $27.13 \%$.

$$
\text { Ans. } \quad \mathrm{C}_{2} \mathrm{H}_{5} \mathrm{NO} .
$$

6. Carbon $46.75 \%$. Hydrogen $6.48 \%$. Nitrogen $36.36 \%$. Oxygen by difference, $10.41 \%$. Ans. $\quad \mathrm{C}_{6} \mathrm{H}_{10} \mathrm{~N}_{4} \mathrm{O}$.
Calculate the formulae of the following minerals.
7. Pyrargyrite. (*) Sulphur $17.8 \mathrm{I} \%$. Antimony $22.45 \%$. Silver $59.75 \%$. Ans. $\mathrm{Ag}_{3} \mathrm{SbS}_{3}$.
8. Enargite. Sulphur $32.69 \%$. Arsenic $19.47 \%$. Copper $47.84 \%$. Ans. $\mathrm{Cu}_{3} \mathrm{AsS}_{4}$.
9. Bournonite. Sulphur $19.36 \%$. Antimony $23.57 \%$. Arsenic $0.47 \%$. Lead $41.95 \%$. Copper $13.27 \%$. Iron $0.68 \%$. Ans. ${ }_{2} \mathrm{PbS}, \mathrm{Cu}_{2} \mathrm{~S}, \mathrm{Sb}_{2} \mathrm{~S}_{3}$ or $3\left(\mathrm{PbCu}_{2}\right) \mathrm{S}, \mathrm{Sb}_{2} \mathrm{~S}_{3}$.
10. Atacamite. Chlorine $16.45 \%$. Copper $14.72 \%$. Copper oxide (CuO) $55.26 \%$. Water $13.57 \%$.

$$
\text { Ans. } \mathrm{Cu}_{2} \mathrm{Cl} \mathrm{H}_{3} \mathrm{O}_{3} .
$$

[^2]11. Barytocalcite. Carbonic acid $29.44 \%$. Barium oxide $50.36 \%$. Calcium oxide $19.22 \%$. Manganous oxide $0.25 \%$. Ans. $\mathrm{BaCO}_{3}, \mathrm{CaCO}_{3}$ or $\mathrm{RCO}_{3}$.
12. Given the following analysis of augite: $\mathrm{SiO}_{2}$ $54.28 \%,-\mathrm{Al}_{2} \mathrm{O}_{3} 0.5 \mathrm{I} \%, \mathrm{Fe}_{2} \mathrm{O}_{3} \mathrm{0} 098 \%, \mathrm{FeO}$ I.91 $\%, \mathrm{MgO}$ $17.30 \%, \mathrm{CaO} 25.04 \%$. Calculate its formula and oxygen ratio. Ans. $\mathrm{CaMgSi}_{2} \mathrm{O}_{6}$ and I:2.
13. Find the type formula and oxygen ratio for a mineral whose composition is $\mathrm{SiO}_{2} \cdot 38.03 \%, \mathrm{Al}_{2} \mathrm{O}_{3}$ $20.83 \%$, $\mathrm{FeO} 36.15 \%, \mathrm{MnO} 2.14 \%, \mathrm{MgO} 0.97 \%$, CaO $2.73 \%$. Ans. $3 \mathrm{RO}, \mathrm{R}_{2} \mathrm{O}_{3}, 3 \mathrm{SiO}_{2}$ and $\mathrm{I}:$ i.
14. The mineral Zirkelite on analysis yielded the following results: $\mathrm{ZrO}_{2} 52.89 \%, \mathrm{TiO}_{2} 14.95 \%, \mathrm{ThO}_{2}$ $7.31 \%, \mathrm{Ce}_{2} \mathrm{O}_{3} 2.52 \%,\left(\mathrm{Y}_{2} \mathrm{O}_{3}\right)$ ? $0.21 \%, \mathrm{UO}_{2} \mathrm{I} .40 \%, \mathrm{FeO}$ $7.72 \%, \mathrm{CaO} 10.79 \%, \mathrm{MgO} 0.22 \%$, loss on ignition $1.02 \%$. What is the formula? (*)

Ans. RO. $2\left(\mathrm{Zr}, \mathrm{Ti}, \mathrm{Th}, \mathrm{O}_{2}\right.$.
Calculate the percentage composition of the following compounds.
15. Potassium Sulphate, $\mathrm{K}_{2} \mathrm{SO}_{4}$.

Ans. K, $44.91 \%$. S, $18.39 \%$. O, $36.70 \%$.
16. Manganous Sulphate, $\mathrm{MnSO}_{4}$.

Ans. Mn, $36.41 \%$ S, $21.22 \%$. O, $42.37 \%$.
17. Lithium Phosphate, $\mathrm{Li}_{3}\left(\mathrm{PO}_{4}\right)$.

Ans. $\mathrm{Li}, 18.17 \%$. P, $26.70 \%$. O, $55.13 \%$.
18. Zinc Pyrophosphate, $\mathrm{Zn}_{2} \mathrm{P}_{2} \mathrm{O}_{7}$.

Ans. $\mathrm{Zn}, 42.91 \%$. P, 20.34\%. O, $36.75 \%$.
19. Urea, $\mathrm{CH}_{4} \mathrm{~N}_{2} \mathrm{O}$ and Ammonium Cyanate, $\mathrm{NH}_{4}$ CNO.
Ans. C, $19.96 \%$. H, $6.71 \%$. N, $46.71 \%$. O, $26.61 \%$. 20. Benzyl Chloride, $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{CH}_{2} \mathrm{Cl}$. Ans. C, $66.40 \%$. $\mathrm{H}, 5.58 \% . \quad \mathrm{Cl}, 28.02$.

[^3]21. Nitrotoluene $\mathrm{C}_{6} \mathrm{H}_{4}\left(\mathrm{NO}_{2}\right) \mathrm{CH}_{3}$.

Ans. C, $61.27 \%$ H, $5.14 \%$ N, $10.24 \%$ O, $23.34 \%$.
22. Indigo $\mathrm{C}_{16} \mathrm{H}_{10} \mathrm{~N}_{2} \mathrm{O}_{2}$.

Ans. C, $73.24 \%$. H, $3.84 \%$ N, $10.71 \%$. О, $12.20 \%$.
23. Potassium ferrocyanide, crystallized, $\mathrm{K}_{4} \mathrm{Fe}(\mathrm{CN})_{6}$, ${ }_{3} \mathrm{H}_{2} \mathrm{O}$. Ans. K, 37.04\%. $\mathrm{Fe}, \mathrm{I} 3.22 \%$. C, $17.03 \%$.

$$
\mathrm{N}, 19.93 \% . \quad \mathrm{H}, \text { г. } 43 \% . \quad \text { О, } 1 \text { I. } 35 \%
$$

24. A sample of ore contained $20 \%$ of lead, $14 \%$ of zinc and $14 \%$ of water. What are the percentages of lead and zinc on the dry basis.

$$
\text { Ans. Lead } 23.25 \% \text {, Zinc } 16.28 \%
$$

25. A clay was partially dried and then contained $\mathrm{SiO}_{2} 50 \%, \mathrm{H}_{2} \mathrm{O} 7 \%$; the original sample contained $12 \%$ of water. What is the percentage of $\mathrm{SiO}_{2}$ in the original sample.

Ans. $47.3 \mathrm{I} \%$.
26. A sample of copper ore contained $18 \%$ of copper and $5 \%$ of water. What would be the percentage of copper when four-fifths of the water were evaporated?

Ans. $18.75 \%$.
27. A rich silver ore, containing $3 \%$ of water gave 2100 ounces per ton of silver. What is the silver in ounces per ton on the dry basis? Ans. 2165 oz .
28. A wet sample of coal gave $6 \%$ of water when dried at $70^{\circ} \mathrm{C}$. This partially dried sample when analyzed showed $1.5 \%$ water, and $1.5 \%$ sulphur. What were the percentages of water and sulphur in the original sample?

$$
\text { Ans. } 7.4 \mathrm{I} \% \text { and } \mathrm{I} .4 \mathrm{I} \%
$$

29. Ten grams of a silicate mineral lost one gram of water when dried at $100^{\circ} \mathrm{C}$. Five grams of the sample dried at $100^{\circ} \mathrm{C}$. lost 0.1 gram when dried at $250^{\circ} \mathrm{C}$. One gram of the sample dried at $250^{\circ} \mathrm{C}$. lost 0.01 gram at a red heat. What was the total percentage of water in the silicate?

Ans. $12.682 \%$.

## CHAPTER III.

## CALCULATIONS OF MIXTURES HAVING A COMMON CONSTITUENT.

To calculate the weights of chlorine and bromine in a mixture of silver chloride and bromide.

If we have a solution containing chlorides and bromides and wish to determine the weights of chlorine and bromine present, we can precipitate these elements by silver nitrate and weigh the resulting mixture of AgCl and AgBr , weight 1.50 grams. Then by scorification or some other method, determine the silver; weight 1.00 gram. We have the atomic weights of silver 107.93, chlorine 35.45 , bromine 79.96 , the weight of the mixture and the weight of the common constituent, silver.

If all the silver were present as chloride the weight would be 1.32845 grams: for as we know the formula and atomic weights we have the proportion

$$
107.93 \text { : } 143.38:: \text { I. : x. }
$$

At. wt. Ag : Mol. wt. $\mathrm{AgCl}::$ wt. $\mathrm{Ag}:$ wt. AgCl , which gives $x=1.32845$, the weight of silver chloride corresponding to the silver found. But we have 1.50 grams of mixed chloride and bromide, hence 1.50-1.32845 or 0.17155 gram is the excess in weight due to the greater atomic weight of bromine and therefore proportional to the weight of bromine present. So to obtain the weight of bromine we have :

$$
79.96-35.45: 79.96:: 0.1715 \quad: x
$$

At. wt. Br - At. wt. Cl : At. wt. $\mathrm{Br}:$ : excess in wt. : wt. Br.
$\mathrm{x}=0.30809$, weight Br . The weight of chlorine will be: Weight silver, chlorine and bromine 1.50000 grams weight silver (1.) and bromine ( 0.30809 ) $\frac{1.30809 \text { grams }}{0.19191 \text { gram }}$

To calculate the chlorine directly: find the weight of silver bromide corresponding to the silver present.

$$
107.93: 187.89:: 1: x . \quad x=1.74085 \text { grams. }
$$

But we have only 1.5 grams of the mixture so $1.74085-$ I. 5 or 0.24085 is the deficiency due to the lower atomic weight of chlorine and proportional to the weight of chlorine present.
Let $y=$ weight of chlorine, then we have

$$
79.96-35.45: 35.45:: 0.2408: x
$$

and $x=0.19179$ the weight of chlorine present, which confirms the result obtained by difference.

It would be more logical to say that the excess in weight is due to the greater molecular weight of AgBr or the deficiency due to the lower molecular weight of AgCl , but this only means the addition of 107.93 in both cases which does not affect the result after subtraction.

Perhaps the following method is more easily comprehended from a mathematical standpoint but it is longer and the use of logarithms is recommended.

Let $\mathrm{x}=$ weight of AgCl and $\mathrm{y}=$ weight of AgBr , then

$$
\frac{107.93}{143.38} x=\text { weight of silver in } \mathrm{AgCl} \text { and }
$$

$\frac{107.93}{187.89} \mathrm{y}=$ weight of silver in AgBr ; so, using the same weights as before we have the two equations,
(1) $x+y=1.50$ and
(2) $\frac{107.93}{143.38} x+\frac{107.93}{187.89} y=1$.
reducing to decimals we have $0.75275 \mathrm{x}+0.57443 \mathrm{y}=\mathrm{I}$ substituting for x its value in terms of y from equation (I) we have

$$
\begin{aligned}
& 0.75275(\mathrm{I} .5-\mathrm{y})+0.57443 \mathrm{y}=\mathrm{I} \quad \text { Solving } \\
& 0.129 \mathrm{I}=0.1783 \mathrm{y} . \quad \mathrm{y}=0.724 \mathrm{I}, \text { wt. } \mathrm{AgBr} .
\end{aligned}
$$

substituting this value in equation ( I ) we get $\mathrm{x}=0.7759$ wt. AgCl , from which by the following proportions,

$$
\begin{aligned}
& \text { 143.38 }: 35.45:: 0.7759: \text { wt. } \mathrm{Cl} \text { and } \\
& \text { 187.89 : 79.96 }:: 0.724 \mathrm{I}: \text { wt. } \mathrm{Br} ;
\end{aligned}
$$

we get wt. Br 0.308 I 5 and wt. Cl 0.19184 gram.
Suppose we have the weight of a mixture of potassium and sodium sulphates, 0.3710 gram, and the weight of $\mathrm{SO}_{3}, 0.200$ gram ; to calculate the weights of $\mathrm{K}_{2} \mathrm{O}$ and $\mathrm{Na}_{2} \mathrm{O}$. Calculate the $\mathrm{SO}_{3}$ all to $\mathrm{Na}_{2} \mathrm{SO}_{4}$,

$$
80.06: 142.16:: 0.2: x . \quad x=0.3551 .
$$

but as we have 0.3710 gram of mixed sulphates, the excess in weight 0.0159 gram is due to the excess in molecular weight of $\mathrm{K}_{2} \mathrm{O}$ over $\mathrm{Na}_{2} \mathrm{O}$ and is therefore proportional to the weight of $\mathrm{K}_{2} \mathrm{O}$, so we have the proportion,

$$
32.2: 94.3:: 0.0159: x . \quad x=0.0466
$$

$\mathrm{K}_{2} \mathrm{O} 0.0466$ gram. $\mathrm{K}_{2} \mathrm{O} .+\mathrm{Na}_{2} \mathrm{O}+\mathrm{SO}_{3}=0.3710$ gram, $\mathrm{SO}_{3} 0.2000$ gram. $\quad \mathrm{K}_{2} \mathrm{O} .+\mathrm{SO}_{3}=0.2466$ gram 0.2466 gram.

$$
\mathrm{Na}_{2} \mathrm{O}=0.1244 \mathrm{gram}
$$

To solve this example by the other method, let $\mathrm{x}=$ weight of $\mathrm{K}_{2} \mathrm{SO}_{4}$ and $\mathrm{y}=$ weight of $\mathrm{Na}_{2} \mathrm{SO}_{4}$, then $\mathrm{x}+\mathrm{y}$ $=0.37$ I.

The molecular weight of $\mathrm{SO}_{3}$ is 80.06 and that of $\mathrm{K}_{2} \mathrm{SO}_{4}$ is 174.36 ; therefore
$\frac{80.06}{174.36} \times$ represents the weight of $\mathrm{SO}_{3}$ present as $\mathrm{K}_{2} \mathrm{SO}_{4}$
and similarly $\frac{80.06}{142.16}$ y the weight of $\mathrm{SO}_{3}$ present as $\mathrm{Na}_{2} \mathrm{SO}_{4}$, so we have for a second equation, $\frac{80.06}{174.36} x+\frac{80.06}{142.16} y=0.2$ or after multiplying and removing unnecessary fractions,

$$
\text { I I } 38 \mathrm{I} .3 \mathrm{x}+\mathrm{I} 3959.3 \mathrm{y}=4957.4
$$

substituting from first equation $x=0.37 \mathrm{I}-\mathrm{y}$ we have I 1381.3 (0.37I-y) + I $3959.3 \mathrm{y}=4957.4$ or $2578.0 \mathrm{y}=734.9$; $\mathrm{y}=0.285 \mathrm{I}$, weight of $\mathrm{Na}_{2} \mathrm{SO}_{4}$ and as $x+y=0.37$ Io. $x=0.0859$, weight of $\mathrm{K}_{2} \mathrm{SO}_{4}$. From which the following proportions will give the weights of $\mathrm{K}_{2} \mathrm{O}$ and $\mathrm{Na}_{2} \mathrm{O}$
94.3 : 174.36 : : wt. $\mathrm{K}_{2} \mathrm{O}: 0.0859$. wt. $\mathrm{K}_{2} \mathrm{O}=0.0464$. 62.1 : 142.16 : : wt. $\mathrm{Na}_{2} \mathrm{O}: 0.285$ r. wt. $\mathrm{Na}_{2} \mathrm{O}=0.1245$.

The following is a more practical example. One gram of commercial sodium bicarbonate gave $\mathrm{CO}_{2}$, 0.5097 gram and $\mathrm{Na}_{2} \mathrm{O}, 0.368 \mathrm{I}$ gram. Calculate the weights of $\mathrm{NaHCO}_{3}$ and $\mathrm{Na}_{2} \mathrm{CO}_{3}$. Let x be the weight of $\mathrm{Na}_{2} \mathrm{CO}_{3}$ and y the weight $\mathrm{NaHCO}_{3}$; then

$$
\begin{aligned}
& \text { (1) } \frac{44}{106.1} x+\frac{44}{84.06} y=0.5097 \text { and } \\
& \text { (2) } \frac{62.1}{106.1} x+\frac{62.1}{168.12} y=0.3681
\end{aligned}
$$

The molecular weight of $\mathrm{NaHCO}_{3}$ is doubled in the second equation as it takes two molecules to give one $\mathrm{Na}_{2} \mathrm{O}$. Reduce the fractional coefficients to the nearest decimals,

$$
\begin{aligned}
& \text { (1) } 0.4147 x+0.5234 y=0.5097 \\
& \text { (2) } 0.5853 x+0.3694 y=0.368 \mathrm{I}
\end{aligned}
$$

substituting for x in the second equation its value in terms of $y$ we get

$$
0.5853 \frac{(0.5097-0.5234 \mathrm{y})}{0.4147}+0.3694 \mathrm{y}=0.368 \mathrm{I}
$$

$0.7192-0.7385 \mathrm{y}+0.3694 \mathrm{y}=0.368 \mathrm{I}$
$0.3691 y=0.351 \mathrm{I} . \quad y=0.95^{12}$, weight of $\mathrm{NaHCO}_{3}$.
Substituting for $y$ in equation (1) 0.9512 we get $0.4147 \mathrm{x}+0.5234(0.9512)=0.5097$ which gives $\mathrm{x}=$ 0.0285 , weight of $\mathrm{Na}_{2} \mathrm{CO}_{3}$.

This problem may also be done as follows: Calculate all the $\mathrm{CO}_{2}$ to $\mathrm{NaHCO}_{3}$, according to the proportion. 44. : 84.06:: 0.5097 : wt. $\mathrm{NaHCO}_{3}$ :
this gives 0.9737 gram ; next calculate the weight of $\mathrm{Na}_{2} \mathrm{O}$ necessary to combine with this to form the 0.9737 gram of $\mathrm{NaHCO}_{3}$. This is 0.35967 gram, but we have present 0.368I gram, which leaves an excess of 0.00843 gram. This must be employed to make as many $\mathrm{NaHCO}_{3}$ molecules into $\mathrm{Na}_{2} \mathrm{CO}_{3}$ molecules as possible and, as one $\mathrm{Na}_{2} \mathrm{O}$ furnishes the sodium oxide necessary to convert $2 \mathrm{NaHCO}_{3}$ into $2 \mathrm{Na}_{2} \mathrm{CO}_{3}$, to find the amount of $\mathrm{Na}_{2} \mathrm{CO}_{3}$ required by the excess of $\mathrm{Na}_{2} \mathrm{O}$ we have :-

$$
\begin{aligned}
& 62 \text {. } 1 \\
& \text { 2 I } 2.2 \\
& \text { Mol. wt. } \mathrm{Na}_{2} \mathrm{O}: 2 \text { (Mol. wt. } \mathrm{Na}_{2} \mathrm{CO}_{3} \text { ) :: } \\
& 0.00843 \text { : x } \\
& \text { wt. } \mathrm{Na}_{2} \mathrm{O} \text { in excess : wt. } \mathrm{Na}_{2} \mathrm{CO}_{3}
\end{aligned}
$$ $x=0.0288$, weight $\mathrm{Na}_{2} \mathrm{CO}_{3}$.

The weight of $\mathrm{Na}_{2} \mathrm{O}$ present as $\mathrm{Na}_{2} \mathrm{CO}_{3}$ is twice the excess found or 0.01686 gram. The rest of the $\mathrm{Na}_{2} \mathrm{O}$, $0.368 \mathrm{I}-0.01686$ or 0.35124 gram is present as $\mathrm{NaHCO}_{3}$. To find this weight:-
$0.35124: x:: 62.1: 168.12 . x=0.9509$, weight of $\mathrm{NaHCO}_{3}$.

These examples show the results to be the same by either method, the figures should be carried out to four decimals or at least three significant figures so that no appreciable error in calculation shall be added to the unavoidable errors of analysis.

FORMATION OF MIXTURES OF DEFINITE COMPOSITION.
Suppose we wish to form 100 lbs . of a mixture containing $10 \%$ of calcium carbonate and we have at our disposal lots containing $7 \%$ and $23 \%$ respectively. How many pounds of each must be taken?

One lot contains $3 \%$ less than the desired mixture, the other $13 \%$ more, so if we take 3 parts of the richer to 13 of the poorer we shall have a mixture containing $10 \%$.

$$
\begin{array}{rll}
3: 16:: x: 100 . & x=18.75 \mathrm{lbs} . & (23 \%) \\
13: 16: & \mathrm{y}: & 100 . \\
\mathrm{y}=8 \mathrm{r} .25 \mathrm{lbs} . & (7 \%) .
\end{array}
$$

When the proportions cannot be seen by inspection the following method can be used :

Given two iron ores, one containing $0.42 \%$ of phosphorus and the other $0.17 \%$. How much of each must be mixed to give ten tons containing $0.20 \%$ of phosphorus? Let $x$ be the weight in tons of the $0.42 \%$ ore and 10 - $x$ the weight of the $0.17 \%$ ore ; then,

$$
\mathrm{x}(0.0042)+(10-\mathrm{x}) 0.0017=10(0.002)
$$

This equation is based on the equality in weight of phosphorus in the sum of the two portions, and in the mixture.

Solving, we get $x=1.2$ tons, $10-x=8.8$ tons.
Given waste mixed acid from nitrating whose composition is $\mathrm{H}_{2} \mathrm{SO}_{4} 62.178 \%, \mathrm{HNO}_{3} 19.066 \%, \mathrm{H}_{2} \mathrm{O}$ 1 $8.756 \%$; sulphuric acid containing $97 \% \mathrm{H}_{2} \mathrm{SO}_{4}$; nitric acid containing $87 \% \mathrm{HNO}_{3}$. What weights of each must

32 FORMATION OF MIXTURES OF DEFINITE COMPOSITION.
be taken to give 1000 lbs. of a mixture containing $61 \% \mathrm{H}_{2} \mathrm{SO}_{4}, 22 \% \mathrm{HNO}_{3}$ and $17 \% \mathrm{H}_{2} \mathrm{O}$ without adding water?

Let x be the weight of waste acid,

$$
\begin{array}{lll}
y & \text { " " } \\
z & \text { " } & \text { sulphuric acid, } \\
\text { nitric acid, }
\end{array}
$$

then $\mathrm{x}(0.6218)$ is the weight of $\mathrm{H}_{2} \mathrm{SO}_{4}$ in the waste acid, $y$ ( 0.97 ) the weight of $\mathrm{H}_{2} \mathrm{SO}_{4}$ in the sulphuric acid, $z$ ( 0.13 ) the weight of water in the nitric acid and so on. iooo lbs. of the desired mixture must contain 6 ro lbs. $\mathrm{H}_{2} \mathrm{SO}_{4}, 220 \mathrm{lbs} . \mathrm{HNO}_{3}$ and I 7 l lbs . of water. We have therefore the following equations based on equality of weight:

$$
\begin{aligned}
& \text { (1) } x(0.6218)+y(0.97)=610 . \\
& (2) x(0.19066)+z(0.87)=220 . \\
& (3) x(0.18756)+y(0.03)+z(0.13)=170 . \\
& y=\frac{610-x(0.6218)}{0.97}=628.8-x(0.641) \\
& z=\frac{220-x(0.19066)}{0.87}=252.7-x(0.2191)
\end{aligned}
$$

substituting in equation (3)

$$
0.18756 x+18.864-0.01923 x+32.85 \mathrm{I}-0.02848 x
$$

$=170$.

$$
\text { O. } 13985 x=118.285 . \quad x=845.68
$$

substituting in equation ( I )

$$
y=\frac{610-(845.68 \times 0.6218)}{0.97} \quad y=86.77
$$

substituting in equation (2)

$$
z=\frac{220-(845.68 \times 0.19066)}{0.87} \quad z=67.54
$$

Proof $845.68+86.77+67.54=999.99$.

## EXAMPLES.

I. Given a mixture of KCl and NaCl : weight I .33 I grams ; and weight of chlorine 0.709 gram. What are the weights of K and Na ?

Ans. K 0.3915 gram. Na 0.2305 gram.
2. Given a mixture of $\mathrm{PbSO}_{4}$ and $\mathrm{BaSO}_{4}$; weight 4 grams; and weight of $\mathrm{SO}_{4} \mathrm{I} .62$ grams. What are the weights of $\mathrm{PbSO}_{4}$ and $\mathrm{BaSO}_{4}$ ?

Ans. $\mathrm{PbSO}_{4} 0.2738$ gram. $\mathrm{BaSO}_{4} 3.7262$ grams.
3. Given a mixture of $\mathrm{HgCl}_{2}$ and HgCl weight 2.35 grams and chlorine 0.45 gram. What is the weight of each chloride?

Ans. HgCl r. 4847 grams. $\mathrm{HgCl}_{2} 0.8653$ gram.
4. Given a mixture of AgI and AgBr ; weight 4.22 grams and weight of silver 2.II grams. What are the weights of iodine and bromine?

Ans Iodine 1.4792 grams. Bromine 0.6308 gram.
5. Given a mixture of $\mathrm{NaHSO}_{4}$ and $\mathrm{KHSO}_{4}$ : weight 0.5 gram and weight $\mathrm{SO}_{4} 0.395$ gram. What are the weights of K and Na ?

Ans. K 0.0148 gram. Na 0.0860 gram.
6. Given a mixture of $\mathrm{K}_{2} \mathrm{CO}_{3}$ and $\mathrm{KHCO}_{3}$; weight I gram and weight $\mathrm{CO}_{2} 0.40$ gram. What is the weight of each carbonate?
Ans. $\mathrm{K}_{2} \mathrm{CO}_{3} 0.3245$ gram. $\mathrm{KHCO}_{3} 0.6755$ gram.
7. Given a mixture of $\mathrm{K}_{2} \mathrm{C}_{4} \mathrm{H}_{4} \mathrm{O}_{6}$ and $\mathrm{KHC}_{4} \mathrm{H}_{4} \mathrm{O}_{6}$ : weight I gram and weight of K 0.30 gram. What is the weight of each tartrate?

Ans. $\mathrm{K}_{2} \mathrm{C}_{4} \mathrm{H}_{4} \mathrm{O}_{6} 0.6668$ gram. $\mathrm{KHC}_{4} \mathrm{H}_{4} \mathrm{O}_{6} 0.3332$ gram.
8. Given a sample of pure dolomite, $\mathrm{MgCO}_{3}$ and $\mathrm{CaCO}_{3}$ : weight I gram and $\mathrm{CO}_{2}$ weight 0.48 gram. Find the weights of CaO and MgO .

Ans. CaO 0.2841 gram. MgO 0.2359 gram.
9. Given a mixture of $\mathrm{CaH}_{4}\left(\mathrm{PO}_{4}\right)_{2}$ and $\mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{2}$ weight I gram and $\mathrm{PO}_{4}$ weight 0.70 gram. Calculate the weight of each phosphate.

$$
\text { Ans. }\left\{\begin{array}{l}
\mathrm{CaH}_{4}\left(\mathrm{PO}_{4}\right)_{2} 0.4402 \text { gram. } \\
\mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{2} \mathrm{O} .5598 \text { gram. }
\end{array}\right.
$$

10. Given a sample of commercial potassium bicarbonate containing 0.4679 gram of $\mathrm{K}_{2} \mathrm{O}$ and 0.4338 gram of $\mathrm{CO}_{2}$ in one gram. How much $\mathrm{KHCO}_{3}$ and $\mathrm{K}_{2} \mathrm{CO}_{3}$ is there present?
Ans. $\mathrm{KHCO}_{3} 0.98$ I I gram. $\mathrm{K}_{2} \mathrm{CO}_{3} 0.0088$ gram.
II. One gram of manganese ore gave on analysis, manganese 0.25 gram and available oxygen 0.05 gram. How much $\mathrm{Mn}_{2} \mathrm{O}_{3}$ and $\mathrm{MnO}_{2}$ is there present? By available oxygen is meant the amount over that necessary to form MnO .

Let $\mathrm{x}=\mathrm{wt} . \mathrm{Mn}_{2} \mathrm{O}_{3}$ and $\mathrm{y}=\mathrm{wt} . \mathrm{MnO}_{2}$ then we have $\frac{109.98}{157.98} \mathrm{x}+\frac{54.99}{86.99} \mathrm{y}=0.25 . \quad$ Ans. $\mathrm{Mn}_{2} \mathrm{O}_{3} 0.2245$. $\frac{16}{157.98} x+\frac{16}{86.99} y=0.05 . \quad \mathrm{MnO}_{2} \quad 0.1482$.
12. Given a sample of argol (crude potassium bitartrate) ; one gram of which gave 0.2336 gram of $\mathrm{K}_{2} \mathrm{O}$ and 0.7310 gram $\mathrm{H}_{2} \mathrm{C}_{4} \mathrm{H}_{4} \mathrm{O}_{6}$. Supposing that there is no other tartrate or potassium salt present, how much $\mathrm{KHC}_{4} \mathrm{H}_{4} \mathrm{O}_{6}$ and $\mathrm{K}_{2} \mathrm{C}_{4} \mathrm{H}_{4} \mathrm{O}_{6}$ is there ?

Let $\mathrm{x}=\mathrm{wt} . \mathrm{K}_{2} \mathrm{C}_{4} \mathrm{H}_{4} \mathrm{O}_{6}$ and $\mathrm{y}=\mathrm{KHC}_{4} \mathrm{H}_{4} \mathrm{O}_{6}$, then we have
$\frac{94.22}{226.29} x+\frac{47.11}{188.19} y=0.2336$ and $\frac{150.09}{226.29} x+\frac{150.09}{188.19}$
$\mathrm{y}=0.73 \mathrm{I} \quad$ Ans. $\left\{\begin{array}{lll}0.9013 & \text { gram } \mathrm{KHC}_{4} \mathrm{H}_{4} \mathrm{O}_{6} \\ 0.0187 & \text { gram } \mathrm{K}_{2} \mathrm{C}_{4} \mathrm{H}_{4} \mathrm{O}_{6}\end{array}\right.$
I3. Given manganese ores containing $47 \%$ and $23 \%$ of manganese respectively. How many pounds of each must be mixed to give a ton containing $39 \%$ of manganese. Ans. $\left\{\begin{array}{r}666.67 \mathrm{lbs} .23 \% \\ \mathrm{I} 333.33 \mathrm{lbs} .47 \%\end{array}\right.$ ore.
14. Suppose we have ten tons of coal containing $3.5 \%$ of sulphur. We have also supplies of coal containing $1.1 \%$ and $1.6 \%$ of sulphur. How much of each shall we add to the ten tons to make 20 tons containing $2.5 \%$ of sulphur? Ans. 2 tons 1.1 $\%$ and 8 tons $1.6 \%$.
15. Given iron ores containing $54 \%$ of iron with $0.60 \%$ of phosphorus and $47 \%$ of iron with $0.20 \%$ of phosphorus. What is the percentage of iron in a mixture of these containing $0.28 \%$ of phosphorus? Ans. $48.4 \%$.
16. Given two alloys: a brass containing copper $65 \%$, zinc $35 \%$ and a German silver containing copper $56 \%$, zinc $24 \%$, nickel $20 \%$. What is the composition of the alloy formed by melting these together in such proportion that it contains zinc $30 \%$ ? (Supposing that there is no loss by oxidation or volatilization during fusion). Ans. Copper $60.90 \%$, zinc $30 \%$, nickel $9.09 \%$.
17. Suppose we wish to form 100 lbs . of an alloy containing copper $70 \%$, zinc $20 \%$, and tin $10 \%$ and we have besides pure copper, a brass, copper $2 / 3$, zinc $1 / 3$ and solder, zinc $1 / 2$, tin $1 / 2$. How much of each must be taken? Ans. Solder 20 lbs ., brass 30 lbs ., copper 50 lbs .
18. Given pure silver and an alloy containing 890 parts of silver and ino parts of copper. How many ounces of each must be taken to form 1000 ounces of an alloy, 925 parts of silver and 75 parts of copper? Ans. 68 r .8 ozs . of alloy, 318.2 ozs . of silver.

## CHAPTER IV.

## CALCULATIONS FROM EQUATIONS.

Chemical reactions are best represented by equations; these are the expression of definite and exact quantitative changes and therefore are the basis of most analytical calculations.

Take for example the simple reaction

$$
\mathrm{BaCl}_{2}+\mathrm{H}_{2} \mathrm{SO}_{4}=\mathrm{BaSO}_{4}+2 \mathrm{HCl},
$$

from a qualitative standpoint this means that, when barium chloride is added to sulphuric acid or the reverse, barium sulphate and hydrochloric acid are formed. This is not all that is shown by the reaction. It shows that one molecule of barium chloride acting on one molecule of sulphuric acid forms one molecule of barium sulphate and two molecules of hydrochloric acid. Now as the relative weights of the different atoms composing the molecules are known, based on oxygen $=16$, we can by adding these together get the relative weights of the molecules; so the reaction becomes,

$$
\begin{aligned}
& \qquad \mathrm{BaCl}_{2}+\mathrm{H}_{2} \mathrm{SO}_{4}=\mathrm{BaSO}_{4}+2 \mathrm{HCl} \\
& \mathrm{I} 37.4+2(35.45)+2(\mathrm{I} .008)+32.06+64= \\
& \mathrm{I} 37.4+32.06+64+ \\
& 2(35.45+\mathrm{I} .008) \text { or } 208.3+98.076=233.46+72.916 ; \\
& \text { which expresses a definite relation by weight. We do } \\
& \text { not know the absolute weight of a molecule but we do } \\
& \text { know very accurately their relative weights; so that these } \\
& \text { proportions are true when expressed in parts by weight; } \\
& \text { and, whatever the unit of the system may be, grains, }
\end{aligned}
$$

grams, pounds, or tons, we shall always have 233.46 parts of barium sulphate and 72.916 parts of hydrochloric acid formed by the action of 208.3 parts of barium chloride on 98.076 parts of sulphuric acid.

Besides showing the products of the reaction and the relations by weight, the equation also represents relations of energy and heat absorbed or evolved. These will be discussed so far as they relate to analytical calculations in subsequent chapters.

Suppose the percentage of $\mathrm{SO}_{3}$ is desired in magnesium sulphate. The salt is dissolved, barium chloride added and the resulting barium sulphate weighed. According to the preceding reaction, for every molecule of $\mathrm{SO}_{3}$ present there will be a molecule of $\mathrm{BaSO}_{4}$ precipitated ; hence to find the weight of $\mathrm{SO}_{3}$, we have: molecular weight of $\mathrm{BaSO}_{4}$ : molecular weight of $\mathrm{SO}_{3}$ : : actual weight of $\mathrm{BaSO}_{4}$ : corresponding weight of $\mathrm{SO}_{3}$, or or

$$
\begin{aligned}
& 233.46: 80.06:: \text { wt. } \mathrm{BaSO} \\
& 4
\end{aligned}: \text { wt. } \mathrm{SO}_{3}{ }_{2}=\text { weight } \mathrm{SO}_{3} .
$$

and to get percentage we have:
weight taken for analysis (magnesium sulphate) : $100:$ : weight $\mathrm{SO}_{3}$ : x
or $\quad \frac{\text { weight } \mathrm{SO}_{3} \times 100}{\text { weight taken }}=$ percentage of $\mathrm{SO}_{3} \cdot(*)$
In the same way this precipitate of $\mathrm{BaSO}_{4}$ can be used to determine the percentage of barium or barium oxide, here we have for barium: molecular weight of

[^4]$\mathrm{BaSO}_{4}$ : atomic weight $\mathrm{Ba}:$ : weight $\mathrm{BaSO}_{4}$ : weight Ba , and for barium oxide:
mol. wt. $\mathrm{BaSO}_{4}$ : mol. wt. BaO : : wt. $\mathrm{BaSO}_{4}$ : wt. BaO . or 233.46 : 153.4 : : wt. $\mathrm{BaSO}_{4}$ : x.
and $\frac{x}{\text { wt. taken for analysis }} \times 100=$ Percentage BaO .
If in this same precipitate the sulphur is desired (for example in coal analysis) we have
$$
233.46: 32.06:: \text { wt. } \mathrm{BaSO}_{4}: x \text { (wt. S.) }
$$

The calculation for lead sulphate will be similar, though the proportion will be different on account of the higher atomic weight of lead. To calculate the weight of lead corresponding to one gram of $\mathrm{PbSO}_{4}$ we have :

$$
\begin{gathered}
\left.302.96 \text { (Mol. wt. } \mathrm{PbSO}_{4} \text { ) : } 206.9 \text { (At. wt. } \mathrm{Pb}\right):: \mathrm{I}: \mathrm{x} . \\
x=0.6829 .
\end{gathered}
$$

Suppose we precipitate $\mathrm{MgNH}_{4} \mathrm{PO}_{4} \cdot 6 \mathrm{H}_{2} \mathrm{O}$, filter, wash, ignite, and weigh. On ignition this is converted into magnesium pyrophosphate, $\mathrm{Mg}_{2} \mathrm{P}_{2} \mathrm{O}_{7}$, which can be used either for the determination of magnesium oxide or phosphoric anhydride. We have the reactions:
$\mathrm{MgCl}_{2}+\mathrm{NH}_{4} \mathrm{OH}+\mathrm{Na}_{2} \mathrm{HPO}_{4}=\mathrm{MgNH}_{4} \mathrm{PO}_{4}+$ ${ }_{2} \mathrm{NaCl}+\mathrm{H}_{2} \mathrm{O}$.
and, $2 \mathrm{MgNH}_{4} \mathrm{PO}_{4}+$ heat $=\mathrm{Mg}_{2} \mathrm{P}_{2} \mathrm{O}_{7}+{ }_{2} \mathrm{NH}_{3}+\mathrm{H}_{2} \mathrm{O}$.
For every molecule of the ignited precipitate there must have been present in the original solution two atoms of magnesium, two atoms of phosphorus or one molecule of $\mathrm{P}_{2} \mathrm{O}_{5}$; so to get the corresponding amount of MgO we have :

Mol. wt. $\mathrm{Mg}_{2} \mathrm{P}_{2} \mathrm{O}_{7}: 2$ (Mol. wt. MgO ) : : wt. ppt. : x.

$$
\text { or } 222.72: 80.72 \quad:: \text { wt. ppt. : x. }
$$

and $\frac{\mathrm{x}}{\text { wt. taken }} \times 100=$ Percentage of MgO .

Similarly to get the corresponding weights of phosphorus or phosphoric anhydride we have :

$$
\begin{gathered}
\mathrm{Mg}_{2} \mathrm{P}_{2} \mathrm{O}_{7}: 2 \mathrm{P}:: \text { : wt. ppt. : } \mathrm{x} . \\
222.72: 6_{2} . \\
\text { and } \mathrm{Mg}_{2} \mathrm{P}_{2} \mathrm{O}_{7}: \mathrm{P}_{2} \mathrm{O}_{5} \\
222 . \text { wt. ppt. : ppt. : y. } \\
222.72: \mathrm{x}^{2} . \\
\text { : : wt. ppt. : y. }
\end{gathered}
$$

The calculations for the pyrophosphates of zinc and of manganese are similar, using the atomic weights of these metals instead of that of magnesium.

Zinc is often weighed as $\mathrm{ZnNH}_{4} \mathrm{PO}_{4}$ : in this case for each molecule of the precipitate there will be but one zinc and the proportion will be

$$
\text { r } 78.47: 65.4:: \text { wt. ppt. : x. }
$$

All direct stoichiometrical calculations are made in this way, using the proper atomic weights and bearing in mind to place in the proportion the weight of the number of atoms or molecules of the constituent sought, which the precipitate or the residue weighed contains.

Indirect Determinations.-In the material weighed the element to be determined may not be present at all.

For example: Potassium is .precipitated quantitatively as $\mathrm{K}_{2} \mathrm{PtCl}_{6}$ : this may be weighed as such or may be ignited with a little oxalic acid, the soluble potassium chloride washed out, and the spongy platinum weighed. The reactions are

$$
2 \mathrm{KCl}+\mathrm{H}_{2} \mathrm{PtCl}_{6}=\mathrm{K}_{2} \mathrm{PtCl}_{6}+2 \mathrm{HCl}
$$

To calculate the weight of $\mathrm{K}_{2} \mathrm{O}$ from the weight of the double chloride we have

Mol. wt. $\mathrm{K}_{2} \mathrm{PtCl}_{6}$ : Mol. wt. $\mathrm{K}_{2} \mathrm{O}:$ : wt. ppt. : x. 485.8 : 94.3 : : wt. ppt. : x.

If platinum is weighed :-each molecule of $\mathrm{K}_{2} \mathrm{PtCl}_{6}$ has one atom of platinum and two of potassium, so for
each atom of platinum weighed there must have been two atoms of potassium, equivalent to a molecule of $\mathrm{K}_{2} \mathrm{O}$ in the solution to cause its precipitation, hence we have

$$
\text { At. wt. Pt : Mol. wt. } \mathrm{K}_{2} \mathrm{O}: \text { : wt. residue : } \mathrm{x}
$$

or 194.8 : $94.3 \quad:$ : wt. residue : $x$
and in either case $\frac{x}{w t . ~ t a k e n} \times 100=$ Percent of $\mathrm{K}_{2} \mathrm{O}$.
It must always be kept in mind that, when there is a change in composition during ignition, it is the formula of what is actually weighed which gives the basis for calculation. For example, cobalt is often separated from nickel by precipitation as $2 \mathrm{Co}\left(\mathrm{NO}_{2}\right)_{3}, 6 \mathrm{KNO}_{2}$ and after filtering, etc., is converted into $\mathrm{CoSO}_{4}$ and $\mathrm{K}_{2} \mathrm{SO}_{4}$ by sulphuric acid. The properties of the double nitrite are studied for the purpose of separation but all calculations are based on the sulphates weighed. To illustrate: One gram of nickel matte was taken for analysis and the mixed sulphates of cobalt and potassium weighed 0.0896 gram. What is the percentage of cobalt? We have the reaction,

$$
\begin{aligned}
& \quad 2 \mathrm{Co}\left(\mathrm{NO}_{2}\right)_{3}, 6 \mathrm{KNO}_{2}+5 \mathrm{H}_{2} \mathrm{SO}_{4}=2 \mathrm{CoSO}_{4}+3 \mathrm{~K}_{2} \mathrm{SO}_{4} \\
& +5 \mathrm{H}_{2} \mathrm{O}+7 \mathrm{NO}_{2}+5 \mathrm{~N}^{2} . \\
& \text { so for every }{ }_{2} \mathrm{CoSO}_{4}+3 \mathrm{~K}_{2} \mathrm{SO}_{4} \text { there must be } 2 \mathrm{Co} \text { or } \\
& 833.2: \text { 118. :: 0.0896: x. x }=0.0127 \text { gram or } \\
& 1.27 \% \text { Co. }
\end{aligned}
$$

## QUANTITY OF REAGENTS.

In analytical as well as technical work it is often necessary to know what quantity of a reagent to add to cause a reaction.

For example. . How much $4 \%$ ammonium oxalate is necessary to precipitate as calcium oxalate the lime in one gram of limestone? We have the reactions;

$$
\begin{gathered}
\mathrm{CaCO}_{3}+2 \mathrm{HCl}=\mathrm{CaCl}_{2}+\mathrm{H}_{2} \mathrm{O}+\mathrm{CO}_{2} \\
\mathrm{CaCl}_{2}+\left(\mathrm{NH}_{4}\right) \mathrm{C}_{2} \mathrm{O}_{4}=\mathrm{CaC}_{2} \mathrm{O}_{4}+2 \mathrm{NH}_{4} \mathrm{Cl} .
\end{gathered}
$$

We see by comparing the two equations that one molecule of $\mathrm{CaCO}_{3}$ requires one of $\left(\mathrm{NH}_{4}\right)_{2} \mathrm{C}_{2} \mathrm{O}_{4}$. So, assuming that the limestone is pure calcium carbonate, we have; Mol. wt. $\mathrm{CaCO}_{3}$ : Mol. wt. $\left(\mathrm{NH}_{4}\right)_{2} \mathrm{C}_{2} \mathrm{O}_{4}$ : : wt. limestone : wt. ammonium oxalate or

$$
\text { 100.I : I24.I4 :: I : x. } \quad x=1.2402 \text { grams, }
$$

but a $4 \%$ (by weight) solution is to be used; to find what weight of solution contains 1.2402 grams of the salt we have

$$
1.2402: x:: 4: \text { ioo. } x=31.005 \text { grams. }
$$

It is not to be inferred that this is necessarily the best amount to add but it is certain that less will be insufficient for complete precipitation.

In the precipitation of zinc as zinc ammonium phosphate, it is considered advisable to add three times the amount of the precipitant actually required. How many grams of a $15 \%$ solution of $\mathrm{NH}_{4} \mathrm{NaHPO}_{4}$ should be added to a solution containing 0.25 gram of zinc? The reaction is :

$$
\begin{aligned}
& \mathrm{Zn}\left(\mathrm{NO}_{3}\right)_{2}+\mathrm{NH}_{4} \mathrm{NaHPO}_{4}+\mathrm{NH}_{4} \mathrm{OH} .= \\
& \mathrm{ZnNH}_{4} \mathrm{PO}_{4}+\mathrm{NH}_{4} \mathrm{NO}_{3}+\mathrm{NaNO}_{3}+\mathrm{H}_{2} \mathrm{O}
\end{aligned}
$$

or one molecule of precipitant for one atom of zinc: Hence to satisfy the equation 0.5245 gram are required for,

$$
\text { 137.1 } 3: 65.4:: x: 0.25 . \quad x=0.5242
$$

The corresponding weight of a $15 \%$ solution is 3.496 grams, for

$$
0.5242: x:: \text { I } 5: 100 . \quad x=3.495
$$

This is the weight of a $15 \%$ solution necessary to satisfy
the equation but we are to add three times this amount or 10.485 grams.

To obtain a $15 \%$ solution of the active constituent: Microcosmic salt contains four molecules of water of crystallization, so to make-say 100 grams of a $15 \%$ solution we must first find what weight of the crystallized salt is required to give 15 grams of the active constituent.
Mol. wt. $\mathrm{NaNH}_{4} \mathrm{HPO}_{4}$ : Mol. wt. $\mathrm{NaNH}_{4} \mathrm{HPO}_{4}, 4 \mathrm{H}_{2} \mathrm{O}:$ :

$$
15: x \text { or 137.13:209.19: }: 15: x . \quad x=22.882
$$

So we must weigh out 22.882 grams and dissolve it in $100-22.882$ grams or 77.118 grams of water.

## to determine which reagent is most economical.

Cases often arise where a reaction can be performed by several reagents, so that it is of importance to use the most economical, not necessarily the lowest priced. For example, which is more economical as an oxidizing agent, potassium chlorate at 8 cents a pound or sodium chlorate at io cents?

One molecule of either will yield three atoms of oxygen, so the oxygen in a pound of $\mathrm{KClO}_{3}$ is $\frac{48}{122.6} \mathrm{lb}$. and the oxygen in a pound of $\mathrm{NaClO}_{3}$ is $\frac{48}{106.5} \mathrm{lb}$. The most economical is the one which gives the most oxygen for one cent. To compare these we have,
$\mathrm{KClO}_{3} \frac{48}{122.6} \div 8$ or 0.04894 lb . for one cent.
$\mathrm{NaClO}_{3} \frac{48}{\text { IO6.5 }} \div 10$ or 0.04507 lb . for one cent.
Which shows potassium chlorate to be more economical at the prices given.

## EXAMPLES.

I. What is the weight of BaO in 1.9327 grams of $\mathrm{BaCrO}_{4}$ ? Ans. I. 1695.
2. What is the weight of CaO in 2.9478 grams of $\mathrm{CaSO}_{4}$ ?

Ans. 1.2 145.
3. What weight of $\mathrm{MnCO}_{3}$ yields on ignition 1.450 grams of $\mathrm{Mn}_{3} \mathrm{O}_{4}$ ? Ans. 2.1845.
4. How much arsenic is there in 5 grams of $\mathrm{As}_{2} \mathrm{~S}_{3}$ ? of $\mathrm{As}_{2} \mathrm{~S}_{5}$ ? of $\mathrm{Mg}_{2} \mathrm{As}_{2} \mathrm{O}_{7}$ ? Ans. (a) 3.0465 , (b) 2.4170 , (c) 2.4135.
5. How much AgI can be made from a pound of pure silver? How much AgBr ? How much AgCl ?

Ans. ${ }^{2} 1753$ lbs. AgI, r. 7409 lbs. AgBr, i. 3285 lbs. AgCl .
6. 1.10 grams of stibnite gave on analysis 0.5987 gram of $\mathrm{Sb}_{2} \mathrm{O}_{4}$. What is the percentage of antimony? Ans. $42.98 \%$.
7. How many pounds of water will it take to slack 100 lbs. of quicklime $(\mathrm{CaO})$ ? Ans. 32.1 lbs.
8. How many pounds of red lead $\left(\mathrm{Pb}_{3} \mathrm{O}_{4}\right)$ can be made from a ton of litharge $(\mathrm{PbO})$ ?

Ans. 2048 lbs.
9. How many grams of $\mathrm{MnO}_{2}$ and of $\mathrm{H}_{2} \mathrm{SO}_{4}$ are required to give 10 grams of oxygen?

Ans. 61.297 grams $\mathrm{H}_{2} \mathrm{SO}_{4}, 54.375$ grams $\mathrm{MnO}_{2}$.
ro. One gram of coal gave 0.2634 gram of $\mathrm{BaSO}_{4}$ by Eschka's method; I gram of MgO and 0.5 gram of
$\mathrm{Na}_{2} \mathrm{CO}_{3}$ were used. It was found that both contained sulphur: io grams of MgO and 5 grams of $\mathrm{Na}_{2} \mathrm{CO}_{3}$ (together) gave 0.1654 gram of $\mathrm{BaSO}_{4}$. What is the percentage of sulphur in the coal? Ans. $3 \cdot 39 \%$.
II. How many pounds of $20 \% \mathrm{H}_{2} \mathrm{SO}_{4}$ will it take to neutralize a ton of $\mathrm{Na}_{2} \mathrm{CO}_{3}$ ? of $\mathrm{NaHCO}_{3}$ ? of $\mathrm{CaCO}_{3}$ ? Ans. (a) 9243.7 lbs ., (b) 5833.8 lbs ., (c) 9797.8 lbs .
12. How many pounds of $10 \% \mathrm{HCl}$ will it take to neutralize a ton of $\mathrm{Na}_{2} \mathrm{CO}_{3}$ ? of $\mathrm{NaHCO}_{3}$ ? of $\mathrm{CaCO}_{3}$ ?

Ans. (a) 13745 lbs., (b) 8674 lbs., (c) 14569 lbs.
13. Suppose one gram of silver is dissolved in nitric acid and to it is added 0.25 gram of pure dry sodium chloride. What percentage of the silver remains-in solution?

Ans. $53.88 \%$.
14. Suppose 0.25 gram of sodium bromide were added to a solution of one gram of silver. What percentage of silver remains in solution?

$$
\text { Ans. } \quad 73.8 \mathrm{I} \%
$$

15. A dolomite contains $98 \%$ of calcium and magnesium carbonates, $2 \%$ of $\mathrm{SiO}_{2}$ and $10 \%$ of MgO . What is the percentage of $\mathrm{CO}_{2}$ ? Ans. $44.79 \%$.
16. One gram of ore containing nickel and cobalt gave 0.2750 gram of metallic nickel and cobalt and 0.2103 gram of sulphates of potassium and cobalt $\left(3 \mathrm{~K}_{2} \mathrm{SO}_{4}, 2 \mathrm{CoSO}_{4}\right)$ What is the percentage of nickel ?

$$
\text { Ans. } \quad 24.52 \% \text {. }
$$

17. One gram of a rock gave on analysis, combined sodium and potassium sulphates 0.150 gram and platinum from $\mathrm{K}_{2} \mathrm{PtCl}_{6} 0.1127$ gram. What are the percentages of $\mathrm{K}_{2} \mathrm{O}$ and $\mathrm{Na}_{2} \mathrm{O}$ ?

$$
\text { Ans. } \quad \mathrm{K}_{2} \mathrm{O} 5.46 \% . \quad \mathrm{Na}_{2} \mathrm{O} 2.14 \%
$$

18. In an iron ore, ferric oxide, alumina and phosphoric acid were precipitated together, ignited and
weighed as $\mathrm{Fe}_{2} \mathrm{O}_{3}, \mathrm{Al}_{2} \mathrm{O}_{3}$ and $\mathrm{FePO}_{4}$. The weight from three grams of ore was 2.4750 grams: the iron was found to be $50.5 \%$ and the phosphorus $0.25 \%$. What is the percentage of $\mathrm{Al}_{2} \mathrm{O}_{3}$ ? Ans. $9.74 \%$.
19. Which is more economical for neutralizing an alkali $60 \% \mathrm{HNO}_{3}$ at 6 cents per pound, or $20 \% \mathrm{HCl}$ at 3 cents per pound?

Ans. HCl .
20. Which is the more economical oxidizing agent $\mathrm{KNO}_{3}$ at 5 cents a pound or $\mathrm{NaNO}_{3}$ at $5 \mathrm{I} / 2$ cents a pound?

Ans. $\mathrm{NaNO}_{3}$.
2 I . Which is the more economical neutralizing agent, $98 \%$ sulphuric acid at 2.85 cents per pound, or $84 \%$ sulphuric acid at 2.35 cents.

Ans. $84 \%$ at 2.35 cents.
22. How many pounds more of $10 \%$ hydrochloric acid will it take to dissolve ioo lbs. of calcium carbonate than 100 lbs . of barium carbonate? Ans. 359.05 lbs .
23. A sample of coal was partially dried losing $7 \%$ of water. One gram of this sample gave 100 milligrams of barium sulphate. What was the percentage of sulphur in the original sample? Ans. 1.277\%.
24. Which is the cheaper source of cyanogen, potassium cyanide $98 \%$ at 28 cents a pound, or a mixture of $\mathrm{KCN} 68 \%$ and $\mathrm{NaCN} 28 \%$ at 30 cents a pound?

Ans. Practically the same. Mixture preferable.
25. An ore contained $10 \%$ of sulphur. If in this determination one tenth of the barium sulphate were reduced to sulphide by the filter paper, and not reconverted to sulphate, what error, expressed in percentage, would result?

Ans. $0.274 \%$.

## CHAPTER V.

## CALCULATION AND USE OF FACTORS.

In gravimetric analysis factor means the number by which the weight of any precipitate or residue is multiplied to give the weight of the constituent desired, whether the constituent is actually present or has previously been combined in a known proportion.

To calculate the factor for $\mathrm{SO}_{3}$ in $\mathrm{BaSO}_{4}$ we have x : I : : Mol. wt. $\mathrm{SO}_{3}$ : Mol. wt. $\mathrm{BaSO}_{4}$ or $\frac{\text { Mol. wt. } \mathrm{SO}_{3}}{\text { Mol. wt. } \mathrm{BaSO}_{4}}$ or $\frac{80.0 \text { ( }}{233.46}$ or 0.3429 .
The factor is the weight of $\mathrm{SO}_{3}$ in one gram of $\mathrm{BaSO}_{4}$ or one hundredth of the percent of $\mathrm{SO}_{3}$ in $\mathrm{BaSO}_{4}$.

To calculate the factors for S and for BaO , we have

$$
\frac{32.06}{233.46}=0.1373 \text { and } \frac{153.4}{233.46}=0.6571 .
$$

Factors are used as follows:-
First, To simplify calculations.
Instead of making the proportion-
Mol. wt. $\mathrm{BaSO}_{4}$ : Atomic wt. S : : wt. $\mathrm{BaSO}_{4}$ : wt. S. we have wt. $\mathrm{BaSO}_{4} \times$ factor (0.I 373 ) $=$ wt. S .
So that if we have a table of factors, the calculation requires only one multiplication, and this can be changed into an addition by the use of logarithms.

These tables will be found at the back of the book.

Second, To avoid or to greatly reduce calculation by weighing out a multiple of the factor for analysis.

If the weight taken in grams equals the factor each milligram of precipitate or residue equals $0.1 \%$ without any calculation. When ten times the factor is taken each milligram equals $0.01 \%$. When one hundred times the factor is used each milligram equals $0.001 \%$ and so on.

This can be proved as follows:-
Suppose we are to determine $\mathrm{SO}_{3}$ in crystallized magnesium sulphate, $\mathrm{MgSO}_{4}, 7 \mathrm{H}_{2} \mathrm{O}$. Weigh out for analysis 3.4293 grams (ten times the factor), dissolve, and then precipitate as $\mathrm{BaSO}_{4}$, in the usual way; the precipitate weighed 1.626 grams, then we have

$$
\frac{1.626 \times 0.3429}{3.429} \times \mathrm{Ioo}=\text { Percentage of } \mathrm{SO}_{3}
$$

but 0.3429 goes into 3.429 ten times and 10 into 100 ten times, so the result in percentage is ten times the weight in grams or $16.26 \%$, or the precipitate contained 1626 milligrams, each of which is therefore equivalent to $0.01 \%$.

Again the factor for S in $\mathrm{BaSO}_{4}$ is 0.13733 . If we weigh out 13.733 grams of pig iron for analysis, each milligram of $\mathrm{BaSO}_{4}$ will be equivalent to $0.001 \% \mathrm{~S}$. For suppose the $\mathrm{BaSO}_{4}$ obtained, weighed 0.0270 gram ; we would have

$$
\frac{0.027 \times 0.13733}{13.733} \times 100=\text { Percent. of } S \text { or } 0.027 \%
$$

So 27 milligrams $=27$ thousandths percent or each milligram $=0.001$ percent. But this is too large an amount to take unless the sulphur is extremely low, so in practice some portion of it is used as $1 / 2,1 / 3$ or 0.4 ; then the weight of $\mathrm{BaSO}_{4}$, expressed in grams, times 2,3 , or 2.5 is the percentage of sulphur without any
further calculation. For example, if for the determination of sulphur, 5.4932 grams is taken, the weight of $\mathrm{BaSO}_{4}$ in grams divided by four and multiplied by ten gives the percentage of sulphur, for the weight 5.4932 is forty times the factor for S in $\mathrm{BaSO}_{4}$. Suppose the actual weight of $\mathrm{BaSO}_{4}$ to 0.200 gram, then

$$
\frac{0.200 \times 0.13733}{5.4932}=0.005 \mathrm{wt.} \mathrm{~S} \text { in one gram, }
$$

and this times 100 gives percentage or $0.5 \%$; which result is $\frac{0.200}{4} \times 10=0.5 \%$.

Inasmuch as these relations are confusing at first, especially when the weights of precipitates are sometimes given in grams, and sometimes in milligrams, the following table may prove useful.

| Weight taken <br> in.Grams. | Weight Precipitate <br> in Grams. | Weight Precipitate in Milligrams. <br> Factor |
| :--- | :--- | :--- |
| Times $100=$ Percent | Factor $\times 5$. <br> Times $20=$ Percent <br> Factor $\times 10$ | Times $10=$ Percent <br> Each $\mathrm{Mg} .=0.1 \%$ |
| Factor $\times 50$ | Times $2=$ Percent | Divided by $50=$ Percent <br> Each $\mathrm{Mg} .=0.02 \%$ |
| Factor $\times 100$ | Divided by $100=$ Percent <br> Each $\mathrm{Mg} .=0.01 \%$ |  |
| Dercent Direct <br> Each $\mathrm{Mg}=0.002 \%$ |  |  |
| Divided by $1000=$ Percent <br> Each $\mathrm{Mg}=0.001 \%$ |  |  |

The use of factors to save time should not be pushed too far, as the time taken in obtaining an exact quantity of some crystallized salts or of drillings may be greater than
that saved in calculation. The examples given have that objection, which however would not apply to an iron ore or coal in which sulphur was to be determined, as the sample would be in a finely pulverized condition. It takes but little longer to weigh out, say exactly I. 3733 grams than exactly one gram, for the time is consumed in getting the exact weight, not in putting the weights on the pan: and when an analysis is repeatedly made, even this time can be saved by using a special weight, the most convenient multiple of the factor.

This system can be very easily applied also to volumetric work, here the amount to be weighed out will be a multiple of the standard (titer) of the solution used. Suppose we have a solution of $\mathrm{KMnO}_{4}$ I c.c. $=0.0056$ gram of iron. If we take for analysis 0.56 gram of iron ore and 55 . I c.c. of $\mathrm{KMnO}_{4}$ are used, the ore contains $55.1 \%$ of iron for

$$
\frac{55.1 \times 0.0056}{0.56} \times 100=55.1 \%
$$

So that when we take for the test a weight equal to hundred times the standard of the solution, each cubic centimeter equals one percent and the burette reading gives percentage direct.

One hundred times the standard may not be the most convenient quantity to take, but this can be readily be adjusted to the particular titration, bearing in mind that, when

and so on.
The plan of adjusting the weight taken to the strength of the solution presents many advantages ove=
the system of adjusting the solution to a certain weight for analysis, when a portion is used for a single determination. This is particularly the case when the standard solution changes in strength and has to be frequently restandardized. If we always use one burette, which is uniformly calibrated, for the particular solution and weigh out a multiple of the standard for analysis, that burette will read percentage: and we do not have to make up the solution to a certain arbitrary strength, which necessitates accurate measuring apparatus, flasks, etc., which agree with the burette. Then if on standing the solution evaporates or undergoes a partial decomposition, it must be readjusted to read percentage when an arbitrary weight is taken, while by weighing out a multiple of the new standard much trouble is saved with no sacrifice of accuracy. It is not to be inferred however that this system is advantageous in all cases, but only for separate determinations such as iron, copper, zinc, etc.

The most important application of the use of factors, is the assay ton system devised by Prof. Chandler. In assaying ores of gold and silver, the precious metals are always reported in ounces Troy per ton of 2000 pounds avoirdupois. If a suitable number of grams, twenty-five for instance, is taken and the gold and the silver weighed in milligrams, a long calculation is required to convert the results to ounces per ton. If however an assay ton 29.1666 grams, is used, the result in gold or silver as weighed in milligrams is ounces to the ton without any calculation.

The assay ton is derived as follows :-
One pound avoirdupois contains 7000 grains.
One ton, 2000 lbs., contains 14,000,000 grains. One ounce Troy contains 480 grains.

Therefore $14,000,000 \div 480$ or $29,166.6$ is the number of Troy ounces in 2000 lbs . avoirdupois; so if we take this number of milligrams for assay ( $29,166.6+$ ), each milligram of gold or of silver found is an ounce Troy to the ton in the ore: for

$$
1: 29,166.6+: ; 480: 14,000,000 .
$$

Therefore the assay ton is $29,166.6+$ milligrams or $29.1666+$ grams.

## EXAMPLES.

1. Calculate the factors for $\mathrm{Na}_{2} \mathrm{O}$ in $\mathrm{Na}_{2} \mathrm{SO}_{4}$ and in NaCl .

Ans. 0.4368 and 0.5308.
2. Calculate the factors for Zn in ZnO , in $\mathrm{ZnNH}_{4}$ $\mathrm{PO}_{4}$ and in $\mathrm{Zn}_{2} \mathrm{P}_{2} \mathrm{O}_{7}$.

Ans. $0.80345,0.3664$ and 0.4291.
3. Calculate the factors for $\mathrm{As}^{\text {in }} \mathrm{As}_{2} \mathrm{~S}_{3}$, in $\mathrm{Mg}_{2} \mathrm{As}_{2} \mathrm{O}_{7}$ and $\mathrm{Ag}_{3} \mathrm{AsO}_{4}$. Ans. $0.6093,0.4827$ and 0.162 I.
4. Calculate the factors for $\mathrm{N}, \mathrm{NH}_{4}$ and $\mathrm{NH}_{4} \mathrm{Cl}$, for weight of platinum from ignition of $\left(\mathrm{NH}_{4}\right)_{2} \mathrm{PtCl}_{6}$. Ans. $0.1441,0.175^{2}$ and 0.5495 .
5. What are the factors for conversion of Cr into $\mathrm{Cr}_{2} \mathrm{O}_{3}$, into $\mathrm{PbCrO}_{4}$ and into $\mathrm{BaCrO}_{4}$ ?

Ans. 1.4606, 6.1996 and 4.8656.
6. (a) What is the factor to convert weight of $\mathrm{BaSO}_{4}$ to corresponding weight of $\mathrm{H}_{2} \mathrm{SO}_{4}$ ?
(b) What is the factor to convert percentage of $\mathrm{K}_{2} \mathrm{O}$ to percentage of $\mathrm{K}_{2} \mathrm{SO}_{4}$ ?

$$
\text { Ans. (a) } 0.42010 \text { (b) } 1.8490 .
$$

7. What are the factors for $\mathrm{K}_{2} \mathrm{O}$ and for KCl in platinum from $\mathrm{K}_{2} \mathrm{PtCl}_{6}$ ?

Ans. 0.48409 and 0.76591.
8. What are the factors for the iron in $\mathrm{Fe}_{2} \mathrm{O}_{3}$ and in $\mathrm{Fe}_{3} \mathrm{O}_{4}$ ? Ans. 0.6996 and 0.7238.
9. One gram of an antimony ore was taken for analysis and the $\mathrm{Sb}_{2} \mathrm{O}_{4}$ resulting weighed 0.3478 gram :
by mistake the factor for $\mathrm{Sb}_{2} \mathrm{~S}_{3}$ was used. What was the error in percentage of antimony?

$$
\text { Ans. } \quad 2.629 \% .
$$

10. An alloy contains $10 \%$ of antimony. One gram of this alloy gives 0.2895 gram of combined oxides of antimony and tin $\left(\mathrm{Sb}_{2} \mathrm{O}_{4}\right.$ and $\left.\mathrm{SnO}_{2}\right)$. What would be the error in percentage of tin if only the factor for $\mathrm{Sb}_{2} \mathrm{O}_{4}$ were used in the calculation? $A n s$. $0.028 \%$.
ir. What weights of spiegel must be taken for analysis so that each milligram of $\mathrm{Mn}_{2} \mathrm{P}_{2} \mathrm{O}_{7}$ shall equal respectively $0.2 \%, 0.1 \%$ and $0.05 \%$ ?

$$
\text { Ans. } 0.19365,0.3873 \text { and } 0.7746
$$

12. What weights of sphalerite must be used so that each milligram shall equal $0.1 \%$ when the zinc is weighed as ZnO , as $\mathrm{ZnNH}_{4} \mathrm{PO}_{4}$ and as $\mathrm{Zn}_{2} \mathrm{P}_{2} \mathrm{O}_{7}$ ?

$$
\text { Ans. } 0.8035,0.3664 \text { and } 0.4291 .
$$

I 3. What weight of steel must be taken so that, when the phosphorus is weighed as $\mathrm{Mg}_{2} \mathrm{P}_{2} \mathrm{O}_{7}$, the weight in grams shall be percentage direct? Ans. 27.8375 .
14. What weight of pig iron must be taken so that the weight of $\mathrm{BaSO}_{4}$ in grams shall be percentage of sulphur when multiplied by three. Ans. 4.5776.
15. What weights of lead ore must be used so that each milligram of $\mathrm{PbSO}_{4}$ shall equal $0.05 \%$, o.I $\%$ and $0.2 \%$ ? Ans. 1.3658, 0.6829 and 0.3415.
16. What weights of limestone must be taken so that each milligram of CaO equals $0.1 \%$ of CaO ? So that each milligram of $\mathrm{CaSO}_{4}$ equals $0.1 \%$ of CaO ?

$$
\text { Ans. } 1 \text { and } 0.4120 .
$$

17. Given a solution of $\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}$, I c.c. $=0.0054$ gram of iron. How much ore must be taken so that each c.c. shall read $0.1 \%, 0.2 \%, 0.3 \%, 0.5 \%, 0.7 \%$ and 1. $\%$ ? Ans. 5.4, 2.7, 1.8, 1.08, 0.7714, 0.54.
18. Given a solution of $\mathrm{K}_{4} \mathrm{Fe}(\mathrm{CN})_{6}$, I c.c. $=0.00896$ gram of zinc. How much ore must be taken so that each c.c. shall equal $2 \%, 1 \%, 0.5 \%, 0.1 \%$ ?

$$
0.4480,0.8960,1.792,8.960 .
$$

19. Calculate the ounces Troy per ton avoirdupois in the following-
(a) One tenth assay ton of copper matte gave gold 1.22 mgs. , silver 30.94 mgs .
(b) Four assay tons of siliceous ore gave gold 0.12 mg ., silver $0.5^{2} \mathrm{mg}$.
(c) One sixth assay ton of a zinc blende gave gold 0.02 mg ., silver 37.72 mgs .

Ans.:
(a) $\left\{\begin{array}{l}\text { 12.2 ozs. Au. } \\ 309.40 \mathrm{ozs} . \mathrm{Ag} .\end{array}\right.$ (b) $\left\{\begin{array}{l}0.03 \mathrm{oz} . \mathrm{Au} . \\ 0.13 \mathrm{oz} . \mathrm{Ag.} .\end{array}\right.$ (c) $\left\{\begin{array}{l}0.12 \mathrm{oz} . \mathrm{Au} . \\ 226.32 \mathrm{ozs} . \mathrm{Ag} .\end{array}\right.$
20. Calculate the number of grams in an assay ton for a long ton ( 2240 pounds).

Ans. $\quad 32.6666$ grams.

## CHAPTER VI.

## CALCULATIONS OF VOLUMETRIC ANALYSIS.

## PART I. GENERAL.

NORMAL SOLUTIONS.
A normal solution is one which contains the hydrogen equivalent of the active constituent in grams per liter. That is, the amount in a liter which brings into reaction I .008 grams of hydrogen, 8 grams of oxygen or their equivalents, whether the reaction be one of oxidation, reduction, precipitation or saturation.

This definition is used by Mohr and by Sutton and is also in very general use in America. In the examples given in this book this system is used. There are however other definitions of normal solutions, which have caused considerable confusion: They are:

First. The molecular weight in grams per liter. This definition possesses some advantages, for example according to Mohr's definition we can have two normal solutions of $\mathrm{KMnO}_{4}$ of different strengths depending on whether it is used in a neutral or in an acid solution; while according to the "molecular weight in grams" this can not happen, on the other hand Mohr's definition has the great advantage that all normal solutions are equivalent cubic centimeter for cubic centimeter. Solutions containing the molecular weight in grams per liter are now much used in physical chemistry under the name gram-molecule.

Second. In the Gay-Lussac method for the determination of silver, used in mints and assay offices, normal
salt solution is the name given to a solution of such strength that one hundred cubic centimeters will exactly precipitate one gram of silver. This is a special use of the word normal and should not be connected in any way with the equivalent system of volumetric analysis.

Under the system we have adopted, it is absolutely essential to have a correct understanding of "the hydrogen equivalent in grams." Suppose we wish to make a normal solution of sodium hydroxide; we have the re-action-

$$
\mathrm{NaOH}+\mathrm{HCl}=\mathrm{NaCl}+\mathrm{H}_{2} \mathrm{O}
$$

What is the amount necessary to bring into reaction one equivalent of hydrogen? Evidently the molecular weight in grams of $\mathrm{NaOH}(40.058)$ for this is the amount necessary to react with 36.458 grams of HCl and so bring into reaction 1.008 grams of hydrogen.

If we wish a normal solution of $\mathrm{Na}_{2} \mathrm{CO}_{3}$ we have $\mathrm{Na}_{2} \mathrm{CO}_{3}+2 \mathrm{HCl}={ }_{2} \mathrm{NaCl}+\mathrm{H}_{2} \mathrm{O}+\mathrm{CO}_{2}$. It is evident that one molecule of $\mathrm{Na}_{2} \mathrm{CO}_{3}$ brings into reaction two atoms of hydrogen, hence a normal solution of $\mathrm{Na}_{2} \mathrm{CO}_{3}$ will be one half of the molecular weight or 53.05 grams per liter.

Similarly a normal solution of hydrochloric acid will contain the molecular weight, 36.458 grams per liter, of sulphuric acid one half the molecular weight, 49.038 grams, and of orthophosphoric acid one third the molecular weight in grams or 32.6747 grams.

One cubic centimeter of any of these acid solutions will exactly saturate one cubic centimeter of any of the alkaline solutions.

In reactions of precipitation the same rule applies we have,-

$$
\begin{aligned}
& \mathrm{AgNO}_{3}+\mathrm{HCl}=\mathrm{AgCl}+\mathrm{HNO}_{3} \text { or } \\
& \mathrm{AgNO}_{3}+\mathrm{NaCl}=\mathrm{AgCl}+\mathrm{NaNO}_{3}
\end{aligned}
$$

A normal solution of silver nitrate contains the molecular weight in grams, 169.97, per liter: for according to the first reaction 1.008 grams of hydrogen would be actually brought into reaction by a liter of this solution and in the second, the weight of sodium equivalent to I. 008 grams of hydrogen. Similarly with, $\mathrm{NH}_{4} \mathrm{SCN}+$ $\mathrm{AgNO}_{3}=\mathrm{AgSCN}+\mathrm{NH}_{4} \mathrm{NO}_{3}$, a normal solution will contain the molecular weight of ammonium thiocyanate in grams per liter or 76.17 grams. To precipitate a salt of a diatomic element such as $\mathrm{BaCrO}_{4}$, we have a normal solution equal to one half the molecular weight in grams per liter ; for $\mathrm{K}_{2} \mathrm{CrO}_{4}, 97.2$ grams ; for $\mathrm{Na}_{2} \mathrm{CrO}_{4}$. 8 I.I. grams.

For convenience we designate a normal solution by N , tenth normal by $\mathrm{N} / 10$, one hundreth normal by $\mathrm{N} / 100$ and so on.

In the original definition of normal solution appears "equivalent to one gram of hydrogen." This can be retained with perfect accuracy if the atomic weights used are calculated on the basis of hydrogen as unity; but as the ratio of hydrogen to oxygen has been found to be I: I5.88 and not 1 : 16 we must adopt either $H=1$ or $\mathrm{O}=\mathrm{I} 6$ as a basis. $\mathrm{O}=\mathrm{I} 6$ is most generally used at present so to make our definition of normal comparable with the present atomic weights, instead of equivalent to one gram of hydrogen, we must substitute, equivalent to 1.008 grams of hydrogen or better equivalent to 8 grams of oxygen. The advantage of the latter definition will appear in the following explanations of normal solutions for oxidation and reduction.

When ferrous iron is oxidized by potassium dichromate we have the reaction $\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}+6 \mathrm{FeCl}_{2}+{ }_{14} \mathrm{HCl}$ $=6 \mathrm{FeCl}_{3}+2 \mathrm{KCl}+2 \mathrm{CrCl}_{3}+7 \mathrm{H}_{2} \mathrm{O}$ : the essential oxidation in this reaction can be expressed as follows -
$\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}$ can be regarded as breaking up into $\mathrm{K}_{2} \mathrm{O}$. $\mathrm{Cr}_{2} \mathrm{O}_{3}$ and 3 O and $6 \mathrm{FeO}+3 \mathrm{O}=3 \mathrm{Fe}_{2} \mathrm{O}_{3}$. Three atoms of oxygen from the $\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}$ oxidize six atoms of ferrous iron as chloride to the ferric condition, or in other words an iron requires one half an oxygen, equivalent to one hydrogen : so for a normal solution, the molecular weight of $\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}$ in grams must be divided by six, since each molecule oxidizes six atoms of iron each equivalent to one atom of hydrogen or one half an atom of oxygen or expressed in the form of a proportion we have :

Mol. wt. $\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}: \mathrm{x}:: 3 \times 16: 8 . \mathrm{x}=49.083$ grams.
With $\mathrm{KMnO}_{4}$ we have $2 \mathrm{KMnO}_{4}+10 \mathrm{IeSO}_{4}+$ $8 \mathrm{H}_{2} \mathrm{SO}_{4}={ }_{5} \mathrm{Fe}_{2}\left(\mathrm{SO}_{4}\right)_{3}+\mathrm{K}_{2} \mathrm{SO}_{4}+2 \mathrm{MnSO}_{4}+8 \mathrm{H}_{2} \mathrm{O}$.

The essential oxidation is $\mathrm{Mn}_{2} \mathrm{O}_{7}+10 \mathrm{FeO}=5 \mathrm{Fe}_{2} \mathrm{O}_{3}$ +2 MnO or $2 \mathrm{KMnO}_{4}$ give 5 oxygen. To calculate the oxygen equivalent we have, $2\left(\mathrm{Mol} . \mathrm{Wt}. \mathrm{KMnO}_{4}\right)=316.3$ grams, gives oxygen, $5 \times 16=80$ grams, hence 316.3 : $x:: 80: 8$ or a normal solution of $\mathrm{KMnO}_{4}$ contains 31.63 grams per liter when used in an acid solution.

The following may make the calculation of $\mathrm{N}_{\mathrm{KMnO}}^{4}$ more easily understood. $2 \mathrm{KMnO}_{4}$ give $\mathrm{K}_{2} \mathrm{O},{ }_{2} \mathrm{MnO}$ and 5 O : the essential part of the oxidation of iron is ${ }_{2} \mathrm{FeO}+\mathrm{O}=\mathrm{Fe}_{2} \mathrm{O}_{3}$.

Two molecules of permanganate furnish 5 atoms of oxygen : two molecules of ferrous oxide, each containing one iron, require one oxygen, equivalent to two hydrogen, so that twice the molecular weight in grams of permanganate furnish the equivalent of 80 grams of oxygen or $10+$ grams of hydrogen. So the normal solution becomes

$$
\frac{2 \times 158.15}{10}
$$

or 3 I .63 grams per litre.

In the Volhard method for manganese we have in a neutral solution the following reaction

$$
\begin{aligned}
2 \mathrm{KMnO}_{4}+3 \mathrm{MnSO}_{4}+ & 2 \mathrm{ZnO} \\
& = \\
5 \mathrm{MnO}_{2} & +\mathrm{K}_{2} \mathrm{SO}_{4}+2 \mathrm{ZnSO}_{4}
\end{aligned}
$$

the essential oxidation is $\mathrm{Mn}_{2} \mathrm{O}_{7}+{ }_{3} \mathrm{MnO}={ }_{5} \mathrm{MnO}_{2}$ or two molecules of $\mathrm{KMnO}_{4}$ give up under these conditions three atoms of oxygen, so to get a normal solution we have $316.3: x:: 48: 8$ or

$$
\mathrm{x}=2 \mathrm{Mol} . \mathrm{Wt.} \div 6=52.717 \text { grams per liter. }
$$

This is one of the very few cases where the molecular weight definition of normal seems preferable, as here we have two normal solutions of different strengths depending on the reaction. As permanganate is usually used in an acid solution, unless expressly stated, normal means 31.63 grams per liter.

Normal reducing solutions are not much employed, but the following will serve as an illustration. We have the reaction

$$
\mathrm{SnCl}_{2}+2 \mathrm{FeCl}_{3}=\mathrm{SnCl}_{4}+2 \mathrm{FeCl}_{2}:
$$

one molecule of $\mathrm{SnCl}_{2}$ removes two atoms of chlorine or what is the same thing reduces two atoms of iron to the ferrous condition. Now two chlorine correspond to one oxygen ; hence one half the molecular weight in grams of stannous chloride will give a normal solution or

$$
189.9: x:: 16: 8 . \quad x=94.95 \text { grams. }
$$

Or more simply in this case, one molecule of $\mathrm{SnCl}_{2}$ is equivalent in reducing power to two atoms of hydrogen, so the normal solution is one half the molecular weight in grams.

To ascertain the strength of any normal solution the reaction in which it is to be used must always be considered and in this way all confusion will be avoided.

For example, potassium dichromate can be used for precipitating barium or lead, as well as for oxidation as already described.

$$
\begin{aligned}
\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7} & +2 \mathrm{BaCl}_{2}+2 \mathrm{NH}_{4} \mathrm{OH} \\
& =2 \mathrm{BaCrO}_{4}+2 \mathrm{KCl}+2 \mathrm{NH}_{4} \mathrm{Cl}+\mathrm{H}_{2} \mathrm{O} .
\end{aligned}
$$

Here one molecule brings into reaction two atoms of barium, each equivalent to two hydrogen, so the normal potassium dichromate for precipitation is one quarter the molecular weight in grams per liter or 73.625 grams ; not 49.083 grams, the normal solution for oxidation.

An advantage of the "equivalent" definition of normal, which deserves attention, is that when the formula of a compound is altered the equivalent is not ; so that whether you consider potassium permanganate as $\mathrm{K}_{2} \mathrm{Mn}_{2}$ $\mathrm{O}_{8}$ or $\mathrm{KMnO}_{4}$, arsenious oxide as $\mathrm{As}_{2} \mathrm{O}_{3}$ or $\mathrm{As}_{4} \mathrm{O}_{6}$ or ferric chloride as $\mathrm{Fe}_{2} \mathrm{Cl}_{6}$ or $\mathrm{FeCl}_{3}$, the number of grams per liter of a normal solution will remain the same. This is made clear by the following reactions.

$$
\begin{aligned}
\mathrm{K}_{2} \mathrm{Mn}_{2} \mathrm{O}_{8}+ & +5 \mathrm{Fe}_{2}\left(\mathrm{SO}_{4}\right)_{2}+8 \mathrm{H}_{2} \mathrm{SO}_{4}= \\
& { }_{5 \mathrm{Fe}_{2}\left(\mathrm{SO}_{4}\right)_{3}}+\mathrm{K}_{2} \mathrm{SO}_{4}+2 \mathrm{MnSO}_{4}+8 \mathrm{H}_{2} \mathrm{O}
\end{aligned}
$$

Now written
$2 \mathrm{KMnO}_{4}+10 \mathrm{FeSO}_{4}+8 \mathrm{H}_{2} \mathrm{SO}_{4}=$

$$
{ }_{5} \mathrm{Fe}_{2}\left(\mathrm{SO}_{4}\right)_{3}+\mathrm{K}_{2} \mathrm{SO}_{4}+2 \mathrm{MnSO}_{4}+8 \mathrm{H}_{2} \mathrm{O}
$$

In either case the same weight of potassium permanganate oxidizes the same weight of iron and normal solutions will be identical for $\mathrm{N}_{2} \mathrm{Mn}_{2} \mathrm{O}_{8}$ will be one tenth the molecular weight, 31.63 grams, and $\mathrm{N} \mathrm{KMNO}_{4}$ one fifth, 3 I. 63 grams. The same applies to ferrous sulphate.

In using normal solutions the following rules are important. Weigh out one tenth the equivalent in grams
of the substance to be determined and the burette reading gives the percentage directly. With $\mathrm{N} / 10$ solutions weigh out one hundreth of the equivalent in grams and the burette shows the percentage directly. To make this clear, suppose we have a normal sulphuric acid solution and we wish to titrate a sample of caustic potash and to express the results in percentage of $\mathrm{K}_{2} \mathrm{O}$. $\mathrm{N} \mathrm{H}_{2} \mathrm{SO}_{4}$ contains $\frac{98.076}{2}$ grams per liter or I. c.c. $=0.049038$ gram of $\mathrm{H}_{2} \mathrm{SO}_{4}$. The equivalent $\mathrm{K}_{2} \mathrm{O}$ is $\frac{94 \cdot 3}{2}$ or 47.15 ; so N $\mathrm{H}_{2} \mathrm{SO}_{4}$ is equivalent to 0.047 I 5 gram $\mathrm{K}_{2} \mathrm{O}$ per c.c. One tenth the equivalent in grams, 4.7 I 5 , is weighed out, dissolved and titrated, requiring 78.2 c.c. of $\mathrm{N} \mathrm{H}_{2} \mathrm{SO}_{4}$. Obtain the percentage by going through the ordinary calculation

$$
\frac{78.2 \times 0.04715}{4.715} \times 100=78.2 \%
$$

It is seen that this is only another way of expressing the fact that when one hundred times the standard is taken for analysis, the burette gives percentage direct. ${ }^{(*)}$

Besides normal solutions we have standard solutions, that is solutions of known strength. Normal solutions are always standard but standard solutions are not always normal. The salt solution used in the mints is standard, but only normal in a particular sense of the word. Most of the solutions used in volumetric analysis are standard and only approximately normal, tenth normal or one hundreth normal. The question of the strength of solutions and whether systematic or not is largely a matter of individual preference, limited by the

[^5]solubility of the reagent and the requirements of the particular analysis to be performed.

In the calculations of volumetric as in gravimetric analysis the basis of calculation is an equation. Unfortunately there are some cases in which the reaction can not be expressed by a simple equation and in these cases standard not normal solutions must be used.

## ADJUSTMENT OF SOLUTIONS.

As this is in no sense a book on volumetric analysis a discussion of the merits of the different liters in practical use is out of place and the calculations are given so as to apply to whatever unit is taken for the volumetric apparatus.

Suppose we have made up ten liters of sulphuric acid approximately normal and find on standardizing that the strength is I c.c. $=0.050$ gram $\mathrm{H}_{2} \mathrm{SO}_{4}$ and that in making the test we have used $50 \mathrm{c} . \mathrm{c}$. of the solution. We have left 9,950 cubic centimeters and the solution is too strong. To find the amount of water to add to make it normal: let $x$ be the volume required so that the solution shall be normal, then $x$ times 0.049038 is the weight of $\mathrm{H}_{2} \mathrm{SO}_{4}$ contained therein ; 9,950 $\times 0.050$ is the weight of $\mathrm{H}_{2} \mathrm{SO}_{4}$ in our solution. These quantities are equal as they will not be affected by dilution therefore we have

$$
9,950 \times 0.050=x \times 0.049038
$$

$x^{-}=10,145.2$ c.c. So the amount of water to be added is $10,145.2-9,950$ or 195.2 c.c. (These cubic centimeters must accord with the liter adopted.)

Suppose the solution gave on standardizing i c.c. $=$ 0.048 gram $\mathrm{H}_{2} \mathrm{SO}_{4}$. The solution is too weak. By a similar method we can find the amount of water in excess and then add the proper quantity of sulphuric acid, we have

$$
9950 \times 0.048=x \times 0.049038 . \quad x=9739.4
$$

The excess of water is therefore $9950-9739.4$ or 210.6 c.c. For the amount of sulphuric acid to be added see Chapter VII.

It will be readily seen that it is much more convenient to make up the solutions too strong rather than too weak.

If we have a solution of say $\mathrm{Na}_{2} \mathrm{CO}_{3}$ which is too weak; find out the amount of water in excess, then calculate the amount of the salt for this volume of water and add it. The change in volume due to the solution of the salt can be neglected.

Example. A solution of $\mathrm{Na}_{2} \mathrm{CO}_{3}$ was found to have a strength I c.c. $=0.047$ gram of $\mathrm{H}_{2} \mathrm{SO}_{4}$. How much $\mathrm{Na}_{2} \mathrm{CO}_{3}$ must be added to two liters to make it normal?

$$
2000 \times 0.047=x \times 0.049038 . \quad x=1,916.9
$$

There are 83.1 c.c. of water in excess. Now, a normal solution of $\mathrm{Na}_{2} \mathrm{CO}_{3}$ contains $\mathrm{I} / 2$ the molecular weight in grams per liter or 53.05 grams, so the amount to be added is

$$
53.05: y:: 1000: 83 . \mathrm{r} . \quad \mathrm{y}=4.4085 \text { grams. }
$$

We may have two standard solutions of a reagent and desire to make a third of a certain intermediate strength - for example suppose we have two solutions of $\mathrm{NH}_{4} \mathrm{SCN}$
(a) I c.c. $=0.01275$ gram of silver
(b) I c.c. $=0.00447$ gram of silver
and we wish to make one liter of a solution equivalent to 10 mgs . of silver per c.c. How much of each shall we mix. Let $x$ be the number of c.c. of (a); then $1000-$ $x=$ number of $c . c$. of $(b):$ and we have

$$
x(0.01275)+(1000-x) 0.00447=10
$$

(as one liter will contain 10 grams if I c.c. contains 10 mgs .) This gives 667.9 c.c. of (a) and 332 .1 c.c. of (b).

If we have a solution of $\mathrm{KMnO}_{4}$ containing 2 grams per liter and a $\mathrm{N} / \mathrm{s}$ solution of the same, to make two liters of $\mathrm{a}^{\mathbb{N}} / 10 \mathrm{KMnO}_{4}$. Let x be the volume of the 2 grams solution in liters and $(2-x)$ the volume of the $\mathrm{N} / 5$ solution ; then $2 x+(2-x) 6.326=2(3.163)$ and $x=$ I. 4623 liters, $(2-x)=0.5377$ liter.

## SUBTRACTION OF EXCESS NECESSARY TO AFFECT THE INDICATOR.

In some titrations, conspicuously that of zinc by potassium ferrocyanide and that of lead by ammonium molybdate, the end point is not very sharp and a considerable excess of the standard solution is used before the indicator is affected. This amount should be determined by running a blank test under the same conditions as to temperature, bulk, acidity \&c., and should be subtracted from the burette reading before calculating the results; for this amount is the excess necessary to affect the indicator and is required when there is no metal present. Other conditions remaining the same this excess is usually proportional to the bulk, but has to be determined for each set of conditions.

This subtraction of the excess necessary to turn the indicator can be omitted when the solution titrated contains nearly the same weight of metal, as well as the same volume \&c., as was used in standardizing, for then this appears in the lower standard of the solution and no appreciable error is introduced. These conditions are however almost impossible to attain with a variety of ores, so that the best plan is to make the subtraction
from every reading, for a color and set of conditions found satisfactory.

The following will illustrate this fact-
A solution of crystallized potassium ferrocyanide was made up for the titration of zinc ores, approximately, 44 grams per liter. To standardize; 200 mgs . of pure zinc were titrated under the standard conditions, using uranium acetate as an indicator. Then a blank was run under the same conditions.
0.200 gram of zinc $+\mathrm{H}_{2} \mathrm{O}, \mathrm{HCl} \& c$ required 20.45 c.c. Blank ( $\mathrm{H}_{2} \mathrm{O}, \mathrm{HCl} \& \mathrm{c}$ ) required $\mathrm{o} .45 \mathrm{c} . \mathrm{c}$.
0.200 gram of zinc required 20 c.c.

$$
\text { ic.c. }=0.0 \text { Io gram of zinc. }
$$

Disregarding the blank the strength becomes

$$
\text { I.c.c. }=0.0097^{8} \text { gram of } z \mathrm{inc} .
$$

We now titrate one gram of an ore and use 21 c.c. : using the blank this gives $20.55 \%$ : disregarding the blank and using the lower standard gives $20.538 \%$. Results close enough for ordinary work. But suppose we now titrate a rich ore, say one gram requires under the same conditions 56 c.c. : using the blank we get $55.55 \%$ and, disregarding the blank and using the lower standard, we get $54.768 \%$. This involves an error not to be disregarded under any circumstances.

The excess necessary to turn the indicator is worthy of consideration in all titrations. It may be too small to be subtracted in some cases, but there are many in which this error is improperly neglected. Some of the discrepancies in alkalimetric titrations by the use of different indicators, might be reduced if not eliminated by making allowance for the excess necessary to give a certain color with the indicator.

## EXAMPLES.

I. Calculate the number of grams per liter to give normal solutions of oxalic acid, of tartaric acid, of acetic acid and of citric acid.

Ans. $\mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4}, 45.008$ grams ; $\mathrm{H}_{2} \mathrm{C}_{4} \mathrm{H}_{4} \mathrm{O}_{6}, 75.024$ grams; $\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}, 60.032$ grams ; $\mathrm{H}_{3} \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{O}_{7}, 64.02 \mathrm{I}$ grams.
2. Calculate the amounts necessary to make two liters of ${ }^{\mathrm{N}} /{ }_{10} \mathrm{NaCl}$ and NaBr . Ans. NaCl 1 I .7 grams; NaBr 20.602 grams.
3. Given a solution of $\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}$, I с.c. $=0.004^{2}$ gram Fe , how many grams per liter of $\mathrm{KMnO}_{4}$ will give a solution of equal strength ?

$$
\text { Ans. } \quad 2.3764 \text { grams. }
$$

4. How many grams of $\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}$ per liter will give a solution equivalent to a $\mathrm{KMnO}_{4}$ solution containing 2.5 grams per liter? Ans. 3.8795 grams.
5. Two liters of $\mathrm{KMnO}_{4}$ solution were made up approximately ${ }^{\mathrm{N}} / 5$. It was found on standardizing that the strength was I c.c. $=0.01175$ gram Fe and 48.2 c.c. were used. How much water must be added to what remains to make it $\mathrm{N} / 5$ ? Ans. 95.5 c.c.
6. How many grams per liter of $\mathrm{KMnO}_{4}$ will give a solution of such strength that 1 c.c. $=1 \%$ of iron when 0.50 gram is taken for analysis?

$$
\begin{equation*}
\text { Ans. } \quad 2.829^{2} \text { grams. } \tag{66}
\end{equation*}
$$

7. How many grams per liter of $\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}$ will give a solution of such strength that 1 c.c. $=1 \%$ of iron when 0.60 gram is taken for analysis?

Ans. 5.2684 grams.
8. How many grams of $\mathrm{Na}_{2} \mathrm{~S}_{2} \mathrm{O}_{3}, 5 \mathrm{H}_{2} \mathrm{O}$ per liter will give a solution such that i c.c. $=0.5 \% \mathrm{Cu}$, when one gram is taken for analysis?

Ans. 19.520 grams.
9. How much water must be added to two liters of $\mathrm{KMnO}_{4}$, I c.c. $=0.0065$ gram iron, to make it ${ }^{\mathrm{N}} / 10$ ? Ans. 325.6 c.c.
10. How much water must be added to three liters of $\mathrm{K}_{4} \mathrm{Fe}(\mathrm{CN})_{6}$, I c.c. $=0.0115$ gram zinc, to make it read percentage directly when one gram is taken for analysis? Ans. 450 c.c.
II. How many grams of $\mathrm{K}_{4} \mathrm{Fe}(\mathrm{CN})_{6}, 3 \mathrm{H}_{2} \mathrm{O}$ must be added per liter to a solution of such strength that I c.c. $=0.0048$ gram of zinc, to make its strength 5 milligrams of zinc per c.c.? Given the composition of the precipitate $\mathrm{K}_{2} \mathrm{Zn}_{3}\left(\mathrm{Fe}(\mathrm{CN})_{6}\right)_{2}$. Ans. 0.8620 gram.

I 2. How much water must be added to 50 grams of HCl sp. gr. 1.15 containing $29.57 \% \mathrm{HCl}$ by weight to make it normal?
$\mathrm{NHCl}=0.036458 \mathrm{gm} . \mathrm{HCl}$ per c.c.
I. 15 sp. gr. $\mathrm{HCl}=29.57 \%$,
$50 \times 0.2957=14.785$ grams HCl ,

$$
\frac{\text { weight }}{\text { sp. gr. }}=\text { volume }
$$

$\therefore \frac{50}{1.15}=43.48$ c.c. volume of HCl .

Let $x=$ volume in c.c. of NHCl containing 14.785 gms. HCl , then

$$
\begin{aligned}
& 36.458: 14.785:: 1000: x . \quad \mathrm{x}=405.53 \text { с.c., } \\
& 405.53-43.48=362.05 \text { c.c. Ans. }
\end{aligned}
$$

I3. How much water must be added to 100 grams of nitric acid ( I .4 sp . gr.) containing $65 \% \mathrm{HNO}_{3}$ by weight to make it ${ }^{\mathrm{N}} / 2$ ? Ans. 1990.4 c.c.
14. How many grams of sulphuric acid containing $87 \% \mathrm{H}_{2} \mathrm{SO}_{4}$ by weight must be diluted to two liters to give a fifth normal solution? Ans. 22.5462 grams.
15. How much NaOH must be added to I .890 liters of NaOH solution, whose strength is I c.c. $=0.045$ gram $\mathrm{H}_{2} \mathrm{SO}_{4}$, to make it normal? How much water to make it ${ }^{\mathrm{N}} / 2$ ?

Ans. 6.172 grams NaOH. 158 r .3 c.c. water.
16. What volumes of $\mathrm{N} / 2$ and of $\mathrm{N} / 1{ }_{10} \mathrm{H}_{2} \mathrm{SO}_{4}$ must be mixed to give two liters of ${ }^{N} / 5 \mathrm{H}_{2} \mathrm{SO}_{4}$ ?

Ans. $1 / 2$ liter ${ }^{\mathrm{N}} / 2$ and $\mathrm{I} / 2$ liters ${ }^{\mathrm{N}} / 10$.
I7. $\mathrm{A}^{\mathrm{N}} /{ }_{10}$ iodine solution is $2 \%$ too strong. How many cubic centimeters of a ${ }^{N} / 100$ iodine solution must be added to one liter to make it right?

$$
\text { Ans. } 22.22 \text { c.c. }
$$

18. Under certain conditions, in the titration of lead by ammonium molybdate, 0.75 c.c. was found necessary to turn the indicator: 0.300 gram of lead took 32 c.c. of the solution (without allowance). If the subtraction of the blank is omitted, what is the error in the titration of one gram of a $60 \%$ ore? Ans. $0.71 \%$.
19. An ammonium molybdate solution was standardized by lead sulphate, without making any allowance for the end point ; $40 \mathrm{c.c}$. were required for 0.55 gram of
lead sulphate. A lead ore was titrated with this solution, 0.5 gram required 12 c.c. If the proper allowance for the end point were 0.7 c.c., what is the true percentage of lead ?

Ans. $21.60 \%$.
20. If the proper allowance for turning the indicator is 0.2 c.c. in titrating chlorine with ${ }^{\mathrm{N}} /{ }_{100} \mathrm{AgNO}_{3}$, what difference will the omission of this allowance make in titrating I litre of water containing 20 parts per million of chlorine? . Ans. .07I parts Cl per million.

## PART II. REACTIONS OF PRECIPITATION AND OF SATURATION.

## PRECIPITATION.

Usually in all cases where either normal or standard solutions are used for precipitation the reaction is simple and the precipitate of definite composition, so that these calculations require no additional explanation. The only cases likely to give trouble are those in which a reagent combines in different and often complex ratios with different metals, so that reasoning by analogy without a knowledge of the exact composition of the precipitate leads to error.

For example, what would be the strength of a normal potassium ferrocyanide solution for precipitating zinc? The reaction in an acid solution and in the absence of ammonium chloride is,
$3 \mathrm{ZnCl}_{2}+{ }_{2} \mathrm{~K}_{4} \mathrm{Fe}(\mathrm{CN})_{6}=\mathrm{K}_{2} \mathrm{Zn}_{3}\left(\mathrm{Fe}(\mathrm{CN})_{6}\right)_{2}+6 \mathrm{KCl} ;$ so two molecules of potassium ferrocyanide bring into reaction three atoms of zinc, each equivalent to two of hydrogen. The normal solution is therefore the molecular weight in grams divided by three or 122.91 grams.

To get this amount of the active reagent we must weigh out 140.93 grams of the crystallized salt as it contains three molecules of water.

How much $\mathrm{K}_{4} \mathrm{Fe}(\mathrm{CN})_{6}, 3 \mathrm{H}_{2} \mathrm{O}$ must be dissolved and diluted to one litre to give a solution of such strength that I c.c. $=0.005$ gram of zinc?

The molecular weight is 422.79. As two molecules precipitate three atoms of zinc we have the proportion

$$
845.58: 196.2:: x: 5 . \quad x=21.549
$$

Ferrocyanide solutions are also used for the precipitation of lead and of cadmium, but the formulæ of the precipitates are approximately

$$
\mathrm{Pb}_{2} \mathrm{Fe}(\mathrm{CN})_{6} \text { and } \mathrm{K}_{2} \mathrm{CdFe}(\mathrm{CN})_{6},
$$

so that all calculations based on simple ratios between the atomic weights will be wrong and the reaction in each case must be made the basis for the computation.

In cases, like the ferrocyanides, where the composition of the precipitate varies with varying conditions in the titration, there is no advantage in using normal solutions.

## ALKALIMETRY AND ACIDIMETRY.

Many of these calculations require no special mention here as they can readily be performed after the explanations already given. Only a few special cases are given in detail.

In order not to complicate these calculations by the use of different indicators, phenolphthalein is used throughout. This indicator acts as follows:

Red with fixed alkalies, colorless with acids, including carbonic. So when acid is run into carbonated alkali the color is discharged when the $\mathrm{Na}_{2} \mathrm{CO}_{3}$ is converted into $\mathrm{NaHCO}_{3}$, but on boiling the color returns
due to the formation of more $\mathrm{Na}_{2} \mathrm{CO}_{3}$ from the $\mathrm{NaHCO}_{3}$, so to get total $\mathrm{Na}_{2} \mathrm{CO}_{3}$, acid must be run in till the solution remains colorless on boiling. The reactions are

$$
\begin{aligned}
\mathrm{Na}_{2} \mathrm{CO}_{3}+\mathrm{HCl} & =\mathrm{NaHCO}+\mathrm{NaCl} \text { and (boiling) } \\
\mathrm{NaHCO}_{3}+\mathrm{HCl} & =\mathrm{NaCl}+\mathrm{CO}_{2}+\mathrm{H}_{2} \mathrm{O} .
\end{aligned}
$$

I. Caustic and Carbonated Alkali.

1. 5 grams of impure caustic potash are dissolved in water, diluted, an excess of barium chloride added and diluted to $400 \mathrm{c.c}$. One hundred cubic centimeters are filtered off and titrated with $\mathrm{N} \mathrm{HCl}, 5.4$ c.c. required. Another 1.5 grams of the sample dissolved and titrated directly with N HCl boiling, for total alkalinity, required 24.6 c.c. What are the weights of KOH and of $\mathrm{K}_{2} \mathrm{CO}_{3}$ ? The first titration gives the caustic alkali in $\frac{1.5}{4}$ grams, for the barium chloride precipitates the carbonate as barium carbonate and with the caustic gives equivalent amount of $\mathrm{Ba}(\mathrm{OH})_{2}$, which is determined by the NHCl . The reactions are

$$
\begin{aligned}
& \mathrm{Na}_{2} \mathrm{CO}_{3}+\mathrm{BaCl}_{2}=\mathrm{BaCO}_{3}+2 \mathrm{NaCl} \text { and } \\
& 2 \mathrm{NaOH}+\mathrm{BaCl}_{2}=\mathrm{Ba}(\mathrm{OH})_{2}+2 \mathrm{NaCl}
\end{aligned}
$$

The total required 24.6 c.c.
The caustic required $21.6 \mathrm{c} . \mathrm{c}$.
The carbonate required $3.0 \mathrm{c} . \mathrm{c}$
$\mathrm{NHCl}=0.056 \mathrm{I}_{58}$ gram KOH per c.c.
$=0.06915$ gram $\mathrm{K}_{2} \mathrm{CO}_{3}$ per c.c.
hence the weights are $\mathrm{KOH}, \mathrm{I} .2 \mathrm{I} 30$ grams and $\mathrm{K}_{2} \mathrm{CO}_{3}$ 0.20745 gram.

## 2. Carbonate and Bicarbonate.

Four grams of commercial sodium bicarbonate are titrated in a cold dilute solution with $\mathrm{N} / 10 \mathrm{H}_{2} \mathrm{SO}_{4}$ til! the red color disappears: used 6.4 c.c.

To one gram of the sample dissolved in water, 20 c.c. of $\mathrm{N}_{2} \mathrm{SO}_{4}$ are added and the solution boiled till all the carbonic acid is expelled, then titrated back with NKOH : requiring 8.I c.c.

What are the percentages of $\mathrm{NaHCO}_{3}$ and of $\mathrm{Na}_{2} \mathrm{CO}_{3}$ ?

The first titration shows one half of the $\mathrm{Na}_{2} \mathrm{CO}_{3}$, so for one gram the $\mathrm{Na}_{2} \mathrm{CO}_{3}$ required $\frac{2 \times 6.4}{4}=3.2$ c.c. of $\mathrm{N} / 10 \mathrm{H}_{2} \mathrm{SO}_{4}$ or 0.32 c.c. $\mathrm{N}_{2} \mathrm{SO}_{4}$. 4
The total $\mathrm{Na}_{2} \mathrm{O}$ required 20-8.1 $=$ I 1.9 c.c. $\mathrm{NH}_{2} \mathrm{SO}_{4}$ so the $\mathrm{NH}_{2} \mathrm{SO}_{4}$ used on the $\mathrm{Na}_{2} \mathrm{O}$ present as $\mathrm{NaHCO}_{3}$ was $11.9-0.32=11.58$ c.c.
The weights corresponding are

$$
\begin{array}{rl}
\mathrm{NaHCO}_{3}+1.58 \times 0.084058 & =0.9734 \text { gram } \\
\mathrm{Na}_{2} \mathrm{CO}_{3} & 0.32 \times 0.05305
\end{array}=0.0169 \text { gram }
$$

or $97.34 \% \mathrm{NaHCO}_{3}$ and $\mathrm{I} .70 \% \mathrm{Na}_{2} \mathrm{CO}_{3}$.
3. Phosphorus from Ammonium Phospho-Molybdate.

The phosphorus is precipitated as $\left(\mathrm{NH}_{4}\right)_{3} \mathrm{PO}_{4}, 12 \mathrm{MoO}_{3}$, under carefully regulated conditions, this is dissolved in a standard alkali solution according to the reaction;

$$
\begin{aligned}
& 2\left(\mathrm{NH}_{4}\right)_{3} \mathrm{PO}_{44} \mathrm{I}_{2} \mathrm{MoO}_{3}+23 \mathrm{Na}_{2} \mathrm{CO}_{3}+\mathrm{H}_{2} \mathrm{O}= \\
& \quad 2\left(\mathrm{NH}_{4}\right)_{2} \mathrm{HPO}_{4}+\left(\mathrm{NH}_{4}\right)_{2} \mathrm{MoO}_{4}+23 \mathrm{Na}_{2} \mathrm{MoO}_{4}+23 \mathrm{CO}_{2} .
\end{aligned}
$$

In practice an excess of the standard $\mathrm{Na}_{2} \mathrm{CO}_{3}$ solution is added then the excess titrated using phenolphtalein as an indicator. The reason that two molecules of the precipitate require 23 and not 24 molecules of $\mathrm{Na}_{2}$ $\mathrm{CO}_{3}$ is that this indicator changes color when two of the three replaceable hydrogens of phosphoric acid have been substituted by alkali, which leaves (from two molecules) two $\mathrm{NH}_{4}$ groups to combine with a molecule of
$\mathrm{MoO}_{3}$ thus leaving 23 instead of 24 molecules of $\mathrm{MoO}_{3}$ to be neutralized by $\mathrm{Na}_{2} \mathrm{CO}_{3}$.

To calculate the grams per liter of $\mathrm{Na}_{2} \mathrm{CO}_{3}$ solution equivalent to one milligram of $\mathrm{P}_{2} \mathrm{O}_{5}$ per cubic centimeter, we have: i.c.c. $=\mathrm{I} \mathrm{mg}$. I liter $=\mathrm{I}$ gram. $2\left(\mathrm{NH}_{4}\right)_{3} \mathrm{PO}_{4}, \mathrm{I}_{2} \mathrm{MoO}_{3}$ contain $\mathrm{IP}_{2} \mathrm{O}_{5}$ hence

Mol. wt. $\mathrm{P}_{2} \mathrm{O}_{5}: 2_{2}\left(\right.$ Mol.wt. $\mathrm{Na}_{2} \mathrm{CO}_{3}$ ) : : $\mathrm{I}: \mathrm{x}$
I42. : 2440.3 : : : x $x=17.185$ grams per liter of $\mathrm{Na}_{2} \mathrm{CO}_{3}$.
4. Sulphuric and Nitric Acids in Mixed Acid.

The analysis of the waste mixed acid from nitrating is sometimes made as follows: 50 grams of the sample are diluted to a liter and ıо. c.c. of this mixture are withdrawn by a pipette which in this case delivered an amount containing exactly 0.4976 gram of the original sample. The sulphuric acid in this is precipitated as $\mathrm{BaSO}_{4}$ and weighed $=0.7093$ gram .

Another portion is titrated for total acidity as follows: Of an approximately N NaOH solution (20.2 c c. $=0.98$ gram $\mathrm{H}_{2} \mathrm{SO}_{4}$ ) 20.2 c.c. are run into a beaker and this is the neutralized by the diluted acid solution. (50 grams to liter.) Suppose 25.75 c.c. are required.

To calculate the percentage of $\mathrm{H}_{2} \mathrm{SO}_{4}$

$$
\frac{0.7093 \times 0.4201}{0.4976} \times 100=59.88 \%
$$

To calculate the percentage of $\mathrm{HNO}_{3}$

$$
25.75 \text { c.c. }=20.2 \text { c.c. } \mathrm{NaOH}=0.98 \text { gram } \mathrm{H}_{2} \mathrm{SO}_{4}
$$

First calculate the total acidity to $\mathrm{H}_{2} \mathrm{SO}_{4}$ :
As 50 grams are contained in 1000 c.c. 25.75 c.c. contain 1.2875 grams for 50: 1000: : x : 25.75 or $\mathrm{x}=$ $\frac{25.75}{20}=1.2875$ grams. Hence the total acidity in terms
of $\mathrm{H}_{2} \mathrm{SO}_{4}$ is $\frac{0.98}{1.2875} \times 100$ or $76.12 \%$ and $76.12 \%$ $59.88 \%$ or $16.24 \%$ is the acidity due to nitric acid but expressed in terms of $\mathrm{H}_{2} \mathrm{SO}_{4}$. As 63.048 parts of $\mathrm{HNO}_{3}$ are equivalent in power of neutralizing NaOH to 49.043 parts of $\mathrm{H}_{2} \mathrm{SO}_{4}$; to determine the percentage of $\mathrm{HNO}_{3}$ we have: 16.24 : x : : 49.038: 63.048. $x=20.88 \%$.

So the composition of the waste acid is
$\mathrm{H}_{2} \mathrm{SO}_{4} 59.88 \%, \mathrm{HNO}_{3} 20.88 \%$.

## EXAMPLES.

1. How many c.c. more of ${ }^{\mathrm{N}} /{ }_{10} \mathrm{AgNO}_{3}$ will it take to precipitate 2 grams of KCl than 2 grams of KI ? Ans. 147.6 c.c.
2. How much more ${ }^{\mathrm{N}} / 2 \mathrm{~K}_{2} \mathrm{CrO}_{4}$ than ${ }^{\mathrm{N}} / 2 \mathrm{Na}_{2} \mathrm{CrO}_{4}$ will it take to precipitate i gram of $\mathrm{BaCl}_{2}$ ?

Prove that it takes same amount.
3. One gram of an ore containing arsenic was treated according to Pearce's method and the arsenic precipitated as $\mathrm{Ag}_{3} \mathrm{AsO}_{4}$; the silver so combined was titrated by $\mathrm{NH}_{4} \mathrm{SCN}$. The amount used was 27.9 c.c. and the strength of the solution I c.c. $=0.007$ gram of silver. What was the percentage of arsenic?

$$
\text { Ans. } 4.52 \%
$$

4. How much crystallized potassium ferrocyanide per liter will give a solution of such strength that each c.c. is equal to $1 \%$ of lead when 0.5 gram of ore is taken for analysis? Given the composition of the precipitate as $\mathrm{Pb}_{2} \mathrm{Fe}(\mathrm{CN})_{6} \quad$ Ans. 5.1086 grams.
5. How many grams more of lead than of cadmium will be precipitated by 25 c.c. of $N / 10$ potassium ferrocyanide solution (for zinc) given the precipitate in the case of cadmium as $\mathrm{K}_{2} \mathrm{CdFe}(\mathrm{CN})_{6}$ ?

$$
\text { Ans. } 0.25116 \text { gram. }
$$

6. How much more N NaOH will it take to neutralize I gram of HCl than I gram HBr ?

$$
\begin{equation*}
\text { Ans. } \quad \text { I } 5.08 \text { c.c. } \tag{75}
\end{equation*}
$$

7. How much more N NaOH will it take to neutralize I gram of $\mathrm{NaHSO}_{4}$ than N KOH to neutralize I gram of $\mathrm{KHSO}_{4}$ ? Ans. 0.99 c.c.
8. How much sodium hydroxide must be added to seven liters of HCl I c.c. $=0.04$ gram HCl to make it normal ? Ans. 27.2422 grams.
9. How many grams of $20 \% \mathrm{HCl}$ must be added to five liters of potassium hydroxide solution, I c.c. $=0.004$ gram of HCl to make it ${ }^{\mathrm{N}} / 10$ ? Ans. 8.855 grams.
10. How much more $N / 10 \mathrm{HBr}$ will it take to neutralize one gram of NaOH than it does of ${ }^{N} / 10 \mathrm{HCl}$ to neutralize I gram of KOH ? Ans. 71.5 c.c.

I I. Given a solution of sodium hydroxide containing exactly 30 grams per liter. How much ${ }^{\mathrm{N}} /{ }_{10} \mathrm{NaOH}$ must be added to one liter to make a $N / 5$ solution? . How much ${ }^{\mathrm{N}} / 2 \mathrm{H}_{2} \mathrm{SO}_{4}$ must be added to a second liter to make a ${ }^{\mathrm{N}} / 10$ solution? Ans. 5489 c.c. I081. 5 c.c.
12. What is the value of N NaOH in terms of phosphorus from ammonium phosphomolybdate?

$$
\text { Ans. o.00I } 3478 \text { gram. }
$$

13. How much water must be added to I liter of ${ }^{\mathrm{N}} / 10$ NaOH so that each c.c. will read o.or $\%$ of phosphorus when I gram of steel is taken for analysis?

$$
\text { Ans. } \quad 347.8 \text { c.c. }
$$

14. Two liters of ${ }^{\mathrm{N}} / 10$ barium hydroxide solution became cloudy by absorption of carbon dioxide; it was filtered in air free from $\mathrm{CO}_{2}$, and the barium carbonate thoroughly washed. The volume of the barium hydroxide solution with washings was 2300 c.c. The weight of $\mathrm{BaCO}_{3}$ was 270 milligrams. How much barium hydroxide must be added to make the solution ${ }^{\mathrm{N}} /{ }_{10}$ again ? Ans. 2.8058 grams.
15. 0.2 gram of a nitrogenous organic compound was heated with soda lime and the $\mathrm{NH}_{3}$ evolved caught in 50 c.c. ${ }^{N} / 10 \mathrm{HCl}$ : the excess of HCl was neutralized by 14 c.c. of $\mathrm{N} / 5 \mathrm{NaOH}$. What was the percentage of nitrogen?

Ans. $15.44 \%$.
16. Twenty grams of an adulterated sample of vinegar, freed from soluble sulphates, required 16 c.c. N NaOH : io grams gave 0.3162 gram of $\mathrm{BaSO}_{4}$. What is the percentage of acetic acid? Ans. $3.177 \%$.
17. 0.4 gram of impure caustic soda required when titrated directly 95 c.c. of ${ }^{N} / 10 \mathrm{HCl}$ : another 0.4 gram was dissolved, an excess of barium chloride added, and then one half titrated, requiring 46 c.c. What are the percentages of NaOH and $\mathrm{Na}_{2} \mathrm{CO}_{3}$ ?

$$
\text { Ans. } \quad\left\{\begin{array}{l}
\mathrm{NaOH} 92.13 \% \\
\mathrm{Na}_{2} \mathrm{CO}_{3} 3.980 \%
\end{array}\right.
$$

18. Two grams of impure potassium bicarbonate required when titrated cold, in a dilute solution, 6 c.c. of ${ }^{\mathrm{N}} /{ }_{10} \mathrm{H}_{2} \mathrm{SO}_{4}$ : two grams when titrated boiling hot required 18 c.c. of $\mathrm{N} \mathrm{H}_{2} \mathrm{SO}_{4}$. What are the percentages of $\mathrm{K}_{2} \mathrm{CO}_{3}$ and of $\mathrm{KHCO}_{3}$ ?

Ans. $4.15 \%$ and $84.13 \%$.
19. Two grams of impure caustic soda were dissolved in water, an excess of barium chloride added and diluted to 500 c.c. ; 100 c.c. was titrated with $\frac{\mathrm{N}}{2} / 2 \mathrm{HCl}$ and required i7 c.c. Another two grams were titrated also with N/2 HCl , boiling, for total alkalinity; 93 c.c. were required. What are the percentages of NaOH and of $\mathrm{Na}_{2} \mathrm{CO}_{3}$ ? Ans. 85.12\%, $10.6 \mathrm{I} \%$.
20. Three grams of commercial sodium bicarbonate were titrated with ${ }^{N} / 5 \mathrm{HCl}$ in a cold dilute solution till the red color disappeared, 4.2 c.c. were required. One
gram of the sample was dissolved in water, diluted largely and 30 c.c. of ${ }^{N} / 2 \mathrm{HCl}$ added, then boiled till all $\mathrm{CO}_{2}$ was expelled, and the excess of acid titrated by ${ }^{\mathrm{N}} / 2 \mathrm{KOH}$ requiring 6.2 c.c. What are the percentages of $\mathrm{Na}_{2} \mathrm{CO}_{3}$ and $\mathrm{NaHCO}_{3}$ ? Ans. $2.97 \%$, and $95.32 \%$.

PART III. REACTIONS OF OXIDATION AND REDUCTION.

## PERMANGANATE CALCULATIONS.

Suppose we have a ${ }^{\mathrm{N}} / 5$ solution of $\mathrm{KMnO}_{4}$; to calculate its strenoth in terms of oxalic acid we have the reactions,

$$
\begin{gathered}
{ }_{2} \mathrm{KMnO}_{4}+10 \mathrm{FeSO}_{4}+8 \mathrm{H}_{2} \mathrm{SO}_{4}= \\
\mathrm{K}_{2} \mathrm{SO}_{4}+2 \mathrm{MnSO}_{4}+5 \mathrm{Fe}_{2}\left(\mathrm{SO}_{4}\right)_{3}+8 \mathrm{H}_{2} \mathrm{O} \\
2 \mathrm{KMnO}_{4}+5 \mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4}+3 \mathrm{H}_{2} \mathrm{SO}_{4}= \\
\mathrm{K}_{2} \mathrm{SO}_{4}+2 \mathrm{MnSO}_{4}+10 \mathrm{CO}_{2}+8 \mathrm{H}_{2} \mathrm{O} .
\end{gathered}
$$

We see that the same quantity of $\mathrm{KMnO}_{4}$ is required for $10 \mathrm{FeSO}_{4}$ as for $5 \mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4} ; 10 \mathrm{FeSO}_{4}$ contains 10 Fe so that as regards $\mathrm{KMnO}_{4}$, $10 \times$ atomic wt. of $\mathrm{Fe}=$ $5 \times$ Mol. wt. $\mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4}$ or we have, Fe standard o.0I II8: oxalic acid standard : : $10 \times 55.9: 5 \times 90.016$ or

$$
\text { O.OIII8 } 8: \mathrm{x}:: 559: 450.08 . \quad \mathrm{x}=0.009002
$$

All these steps are not necessary however, all we need do is to consider the strength of $\mathrm{N} / 5$ oxalic acid, then this will be equivalent c.c. per c.c. to ${ }^{N} / 5 \mathrm{KMnO}_{4}$. From the reaction we see that one $\mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4}$ requires one O : therefore the amount necessary to bring into reaction eight grams of oxygen will be one half the molecular weight in grams per liter and for ${ }^{\mathrm{N}} / 5$ one tenth the molecular weight or 9.0016 grams, so that I c.c. will be equal to 0.009002 gram.

Many metals are precipitated as normal oxalates such as calcium, barium, lead, cadmium, etc. (not bismuth). In such cases the metal combined with the oxalic acid can be determined indirectly by decomposing the precipitate with sulphuric acid and titrating the oxalic acid set free. To calculate the standard of the permanganate solution we need only remember that 1 CaO or IPb corresponds to one oxalic acid. So as ${ }^{\mathrm{N}} / 5$ oxalic acid was one tenth the molecular weight in grams, ${ }^{N} / 5 \mathrm{CaO}$ will also be one tenth, or 5.6 I grams, or ${ }^{\mathrm{N}} / 5 \mathrm{KMnO}_{4}$ is equivalent to 0.0056 I gram of CaO per c.c. ; very nearly one half the iron standard.

To calculate the strength of ${ }^{\mathrm{N}} / \mathrm{KMnO}_{4}$ in terms of molybdic oxide we have the oxidation of $\mathrm{Mo}_{2} \mathrm{O}_{3}$ to $\mathrm{MoO}_{3}$ or two $\mathrm{MoO}_{3}$ require 3 oxygen, and we have

$$
288: x:: 48: 8 . \quad x=48
$$

Therefore $\mathrm{N} \mathrm{MoO}_{3}$ would have one third the molecular weight in grams per liter ( 48 grams) and $\mathrm{N} / \mathrm{s}$ one fifteenth ( 9.6 grams) per liter or I c.c. $=0.0096$ gram $\mathrm{MoO}_{3}$.

The determination of phosphorus by $\mathrm{KMnO}_{4}$ is indirect for as the ratio of $\mathrm{MoO}_{3}$ to P in the ammonium phospho-molybdate is 12 to I , for every $144 \times 12$ grams of $\mathrm{MoO}_{3}$ found by titration there must be 3 I grams of phosphorus present : so we have $\mathrm{MoO}_{3}$ standard: P standard as 1728:31 or I c.c. ${ }^{\mathrm{N}} / 5 \mathrm{KMnO}_{4}=0.0001722$ gram of phosphorus.

To calculate this value for a standard $\mathrm{KMnO}_{4}$ solution not normal when the iron standard is known : we have

$$
\begin{array}{lr}
6 \mathrm{KMnO}_{4}=10 \mathrm{MoO}_{3} & \text { and } \\
6 \mathrm{KMnO}_{4}=30 \mathrm{Fe} & \text { hence }
\end{array}
$$

$10 \mathrm{MoO}_{3}$ correspond to 30 Fe and the Fe standard: $\mathrm{MoO}_{3}$ standard :: $1677: 1440$ and as the phosphorus standard is $1.794 \%$ of the $\mathrm{MoO}_{3}$ standard, the phosphorus standard will be $1.54 \%$ of the Fe standard or the Fe standard times 0.01540.

The degree of reduction obtained in a reductor is not that just given but corresponds very closely to $\mathrm{Mo}_{2}{ }_{4} \mathrm{O}_{37}$, so that the molybdenum and phosphorus standards are slightly higher than when the complete reduction to $\mathrm{Mo}_{2} \mathrm{O}_{3}$ is effected.

To calculate these values for ${ }^{\mathrm{N}} / 10 \mathrm{KMnO}_{4}$ we have
I $\mathrm{Mo}_{24} \mathrm{O}_{37}$ requires 35 oxygen equivalent to 70 iron I4 $\mathrm{KMnO}_{4}$ give 35 oxygen equivalent to 70 iron $\mathrm{N} /{ }_{10} \mathrm{KMnO}_{4}=\mathrm{I} / 50 \mathrm{~mol}$. weight in grams per litre
$\mathrm{N} /{ }_{10} \mathrm{Mo}_{24} \mathrm{O}_{37}=\frac{\mathrm{I}}{14 \times 5 \mathrm{O}} \mathrm{mol}$. weight in grams per litre so to calculate the molybdenum standard of ${ }^{N} / 10 \mathrm{KMnO}_{4}$ per c.c. we have
$\frac{96 \times 24}{14 \times 50 \times 1000}$ or 0.0032914 gram molybdenum.
To derive this from the iron standard, we have 24 Mo equivalent to 70 Fe , hence
$24 \times 96: 70 \times 55.9:: x: 0.00559 . \quad x=0.0032914$.
To obtain the phosphorus standard, we have from the ratio of molybdenum to phosphorus in the "yellow precipitate"

$$
\begin{aligned}
& \text { 12 } \times 96: 31:: \text { Mo standard }: P \text { standard } \\
& \text { or } 1152: 31:: 0.0032914: y . \\
& y=0.00008857 \text { gram phosphorus per c.c. }
\end{aligned}
$$

A rather confusing calculation is met in the FordWilliams method for manganese: here the manganese
is precipitated as hydrated $\mathrm{MnO}_{2}$ and its oxidizing power measured. Suppose we take for analysis one gram of pig iron, and to the precipitate of $\mathrm{MnO}_{2}$ add 25 c.c. of ${ }^{\mathrm{N}} /{ }_{10} \mathrm{FeSO}_{4}$ and then titrate the $\mathrm{FeSO}_{4}$ remaining unoxidized by ${ }^{\mathrm{N}} / 10 \mathrm{KMnO}_{4}$, using 12 c.c. What is the percentage of manganese?

The reactions are

$$
\begin{aligned}
& \mathrm{MnO}_{2}+2 \mathrm{FeSO}_{4}+2 \mathrm{H}_{2} \mathrm{SO}_{4}= \\
& \mathrm{MnSO}_{4}
\end{aligned}+\mathrm{Fe}_{2}\left(\mathrm{SO}_{4}\right)_{3}+2 \mathrm{H}_{2} \mathrm{O} .
$$

and the usual reaction between the excess of ferrous sulphate and permanganate. The solutions used were both ${ }^{\mathrm{N}} / 10$ and therefore correspond c.c. for c.c., so that the oxidation done by the $\mathrm{MnO}_{2}$ was equal to that which would have been done by is c.c. of ${ }^{\mathbb{N}} /{ }_{10} \mathrm{KMnO}_{4}$. Now we have

$$
\begin{aligned}
{ }_{2} \mathrm{KMnO}_{4} & =10 \mathrm{Fe}, \\
1 \mathrm{MnO}_{2} & ={ }_{2} \mathrm{Fe}
\end{aligned}
$$

Hence ${ }_{2} \mathrm{KMnO}_{4}$ are equivalent to $5 \mathrm{MnO}_{2}$ or to ${ }_{5} \mathrm{Mn}$ and we have Fe standard : Mn standard :: 10 times at. wt. Fe : 5 times at. wt. Mn or 0.00559 : x :: 559. : 275 $x=0.00275$. The percentage of manganese will be 13 (number of c.c. of $\mathrm{KMnO}_{4}$ not required)

$$
\times 0.00275 \div \mathrm{I} \times 100 \text { or } 3.575 \% \mathrm{Mn} .
$$

Oxalic acid may be used in the same method instead of ferrous sulphate to measure the oxidizing power of the precipitate and the excess titrated by permanganate. Suppose one gram of spiegel is taken for analysis and that we have a $\mathrm{KMnO}_{4}$ solution (not systematic) whose strength is I c.c. $=0.006$ gram of iron. We make up a solution of oxalic acid and find that it requires 25 c.c.
of the $\mathrm{KMnO}_{4}$ solution to oxidize 20 c.c. of the oxalic acid solution. To the precipitate (hydrated $\mathrm{MnO}_{2}$ ) from one gram of spiegel, 8o c.c. of the oxalic acid solution are added and, after the complete solution of the precipitate, the excess is titrated by $\mathrm{KMnO}_{4}$, this requires 12 c.c. To calculate the percentage of manganese. If there had been no $\mathrm{MnO}_{2}$ present the 80 c.c. of oxalic acid would have required 100 c.c. of $\mathrm{KMnO}_{4}$, but only 12 were needed, therefore the oxidation done by the $\mathrm{MnO}_{2}$ present was equal to that of 88 c.c. of $\mathrm{KMnO}_{4}$. Now the manganese standard of our $\mathrm{KMnO}_{4}$ is

$$
0.006: x:: 559: 275 \text { or } 0.002952
$$

and

$$
88 \times 0.00295^{2} \div 1 \times 100=25.98
$$

the percentage of manganese.
The peculiar part of this method is that it is the amount of $\mathrm{KMnO}_{4}$ not used which is the basis of calculation.

The problem of making a potassium dichromate solution equivalent to an unsystematic permanganate solution sometimes gives trouble. Suppose we wish to make up two liters of dichromate equivalent in oxidizing power to a permanganate solution containing three grams per liter, how much $\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}$ is to be weighed out? The molecular weight of $\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}$ is 294.5 ; 294.5 grams oxidize $6 \times 55.9$ grams of iron.

The molecular weight of $\mathrm{KMnO}_{4}$ is 158.15 ; 158.15 grams oxidize $5 \times 55.9$ grams of iron.

We must calculate the weight of $\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}$ equal in oxidizing power to six grams of $\mathrm{KMnO}_{4}$ :

$$
6: x:: \frac{158.15}{5}: \frac{294.5}{6} \quad x=9.3108
$$

## IODINE CALCULATIONS.

Tenth normal iodine solution, 12.685 grams per liter, can be used for a great many titrations. For example, in the determination of $\mathrm{H}_{2} \mathrm{~S}$ and so of sulphur in pig iron, \&c. The reaction is

$$
\mathrm{H}_{2} \mathrm{~S}+2 \mathrm{I}=\mathrm{S}+2 \mathrm{HI} .
$$

Five grams of pig iron evolved, on treatment with hydrochloric acid, $\mathrm{H}_{2} \mathrm{~S}$, which when titrated in a dilute solution with starch as indicator required 6.2 c.c. of $\mathrm{N} / 10$ iodine solution. What is the percentage of sulphur? $\mathrm{N} / 10 \mathrm{I}=0.012685$ gram I per c.c. $=0.001603$
gram S per c.c. $\frac{6.2 \times 0.0016}{5} \times 100=0.198 \% \mathrm{~S}$.
Iodine reacts with $\mathrm{H}_{2} \mathrm{SO}_{3}$ as follows:

$$
\mathrm{I}_{2}+\mathrm{H}_{2} \mathrm{SO}_{3}+\mathrm{H}_{2} \mathrm{O}=2 \mathrm{HI}+\mathrm{H}_{2} \mathrm{SO}_{4}
$$

and with $\mathrm{Na}_{2} \mathrm{~S}_{2} \mathrm{O}_{3}$ according to the reaction,

$$
\mathrm{I}_{2}+2 \mathrm{Na}_{2} \mathrm{~S}_{2} \mathrm{O}_{3}=2 \mathrm{NaI}+\mathrm{Na}_{2} \mathrm{~S}_{4} \mathrm{O}_{6}
$$

we see therefore that one iodine is equivalent to $1 / 2 \mathrm{SO}_{2}$, $1 / 2 \mathrm{H}_{2} \mathrm{SO}_{3}$ or $1 / 2 \mathrm{Na}_{2} \mathrm{SO}_{3}$ and to one $\mathrm{Na}_{2} \mathrm{~S}_{2} \mathrm{O}_{3}$.

The latter reaction can be employed for the determination of copper as follows:
${ }_{2} \mathrm{Cu}\left(\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right)_{2}+4 \mathrm{KI}=\mathrm{Cu}_{2} \mathrm{I}_{2}+\mathrm{I}_{2}+4 \mathrm{KC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$ and taking the last two reactions we see that one molecule of $\mathrm{Na}_{2} \mathrm{~S}_{2} \mathrm{O}_{3}$ equivalent to one iodine is equivalent to one copper, so if we have a ${ }^{\mathrm{N}} / 10$ iodine solution we can use it to standardize a sodium thiosulphate solution and so indirectly determine copper by measuring the iodine liberated.

Suppose we have an iodine solution of unknown strength and a potassium dichromate solution whose strength is I c.c. $=0.00559$ gram of iron. To find the strength of our iodine solution in terms of sulphur.

Make up a sodium thiosulphate solution of any convenient strength say 24.8 grams of the crystallized salt $\left(\mathrm{Na}_{2} \mathrm{~S}_{2} \mathrm{O}_{3} \cdot 5 \mathrm{H}_{2} \mathrm{O}\right)$ per liter, approximately $\mathrm{N} / 10$.

Dissolve one gram of potassium iodide in water, acidify strongly with HCl and add 25 c.c. of the dichromate solution. Iodine will be liberated according to the reaction
$\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}+6 \mathrm{KI}+{ }_{14} \mathrm{HCl}=3 \mathrm{I}_{2}+8 \mathrm{KCl}+\mathrm{Cr}_{2} \mathrm{Cl}_{6}+7 \mathrm{H}_{2} \mathrm{O}$ or the amount of $\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{i}$ which oxidizes 6 Fe liberates 6 I ; therefore the strength of the $\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{\tau}$ solution is i.c.c. $=0.012685$ gram of iodine and the weight of iodine liberated will be $25 \times 0.012685$ or 0.3171 gram.

Into this we run the sodium thiosulphate solution till it gives no blue color with starch ; suppose this requires 25.5 c.c. then i.c.c. $=0.01243$ gram of iodine. Now take any convenient amount of the unknown iodine solution as 25 c.c. and titrate it with the sodium thiosulphate solution; suppose it requires 12.2 c.c. then its strength in terms of iodine is $\frac{12.2 \times 0.01243}{25}$ or 0.006066 and against sulphur when titrated as $\mathrm{H}_{2} \mathrm{~S}$,

$$
0.006066: x:: \text { I } 26.85: \text { i } 6.03
$$

$$
\mathrm{x} \text { or } \mathrm{I} \text { c.c. }=0.000767 \text { gram sulphur. }
$$

Arsenic is determined by iodine according to the reaction :

$$
\begin{aligned}
& \mathrm{Na}_{3} \mathrm{AsO}_{3}+\mathrm{I}_{2}+2 \mathrm{NaHCO}_{3}= \\
& \mathrm{Na}_{3} \mathrm{AsO}_{4}+2 \mathrm{NaI}+\mathrm{H}_{2} \mathrm{O}+{ }_{2} \mathrm{CO}_{2}
\end{aligned}
$$

from which it is evident that $2 \mathrm{I}=\mathrm{IAs}$ or 1 c.c. ${ }^{N} / 10$ $\mathrm{I}=0.00375$ gram of arserfic or 0.00495 gram of $\mathrm{As}_{4} \mathrm{O}_{6}$. The available chlorine in bleaching powder can be determined according to a similar reaction by usirg a solution of $\mathrm{Na}_{3} \mathrm{AsO}_{3}$, which can conveniently be standardized by the $\mathrm{N} / 10$ iodine.

Antimony may be determined by sodium thiosulphate in a hydrochloric acid solution as follows :

$$
\begin{gathered}
\mathrm{H}_{3} \mathrm{SbO}_{4}+{ }_{5} \mathrm{KI}+5 \mathrm{HCl}=\mathrm{SbI}_{3}+\mathrm{I}_{2}+{ }_{5} \mathrm{KCl}+4 \mathrm{H}_{2} \mathrm{O} \\
\mathrm{I}_{2}+{ }_{2} \mathrm{Na}_{2} \mathrm{~S}_{2} \mathrm{O}_{3}=2 \mathrm{NaI}+\mathrm{Na}_{2} \mathrm{~S}_{4} \mathrm{O}_{6} .
\end{gathered}
$$

Suppose we have a solution of $\mathrm{Na}_{2} \mathrm{~S}_{2} \mathrm{O}_{3}$ whose strength is I c.c. $=0.005$ gram Cu. What is its strength in terms of antimony?
We see by comparing the reactions that ${ }_{2} \mathrm{Cu}=\mathrm{I}_{2}$ and $\mathrm{I} \mathrm{Sb}=\mathrm{I}_{2}$ hence

$$
0.005: x:: 63.6: 60.1 . \quad x=0.00472 \text { gram. }
$$

If the sodium thiosulphate were $\mathrm{N} / 10$ we should see at once its strength against copper and antimony, for one atom of copper brings into reaction one iodine equivalent to one half atom of oxygen or $\mathrm{a}^{\mathrm{N}} / 10$ solution of $\mathrm{Cu}=$ 6.36 grams per liter; while $1 \mathrm{Sb}=2 \mathrm{I}=\mathrm{I}$ oxygen. So

$$
\begin{aligned}
{ }^{\mathrm{N}} / 10 \mathrm{Sb}=120.2 \div(2 \times 10) & =6.01 \text { grams and } \\
\mathrm{I} \text { c.c. }{ }^{\mathrm{N}} / 10 \mathrm{Na}_{2} \mathrm{~S}_{2} \mathrm{O}_{3} & =0.00636 \text { gram } \mathrm{Cu} \\
& =0.00601 \text { gram Sb. }
\end{aligned}
$$

Similarly, but in a more strongly acid solution arsenic acid, $\mathrm{H}_{3} \mathrm{AsO}_{4}$ liberates iodine being itself reduced to the arsenious condition. The strength of $N / 10$ sodium thiosulphate would be I c.c. $=0.00375$ gram of arsenic. When antimony is oxidized from the triad to the pentad condition in a solution alkaline with bicarbonate the calculation is the same as that already given for arsenic, so that each c.c. of $\mathrm{N} / 10$ iodine is equivalent to 0.00601 gram of antimony.

## REDUCTION BY STANDARD SOLUTIONS.

How many grams of tin must be dissolved in hydrochloric acid and diluted to one liter, to give a solution of
such strength that each c.c. will be equivalent to $1 \%$ of iron when 0.5 gram is taken for analysis?

In order to read percentage from the burette, each c.c. must reduce 0.005 gram of iron, each litre 5 grams : from the reaction, $\mathrm{SnCl}_{2}+2 \mathrm{FeCl}_{3}=\mathrm{SnCl}_{4}+2 \mathrm{FeCl}_{2}$, we see that one molecule of stannous chloride containing one atom of tin reduces two atoms of iron; so the proportion is

$$
5: x:: 55.9 \times 2: \text { 119. } \quad x=5.3220
$$

How many grams per liter of Mohr's salt $\left(\mathrm{NH}_{4}\right)_{2} \mathrm{SO}_{4}$, $\mathrm{FeSO}_{4}, 6 \mathrm{H}_{2} \mathrm{O}$, will give a solution equivalent to ${ }^{\mathrm{N}} / 10$ $\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}$ ? As all ${ }^{\mathrm{N}} /{ }_{10}$ solutions are equivalent the problem is to calculate the number of grams for a ${ }^{\mathrm{N}} / 10$ solution of Mohr's salt. One molecule of Mohr's salt contains one FeO , which requires for oxidation half an atom of oxygen, equivalent to one atom of hydrogen, hence the normal solution is the molecular weight in grams, and the N/10 39.226 grams per liter.

## EXAMPLES.

I. Calculate the strength of ${ }^{\mathrm{N}} /{ }_{20} \mathrm{KMnO}_{4}$ to be used in titrating $\mathrm{K}_{4} \mathrm{Fe}(\mathrm{CN})_{6}$.

Ans. $\quad$ 1.5815 grams per liter.
2. What is the strength of ${ }^{\mathrm{N}} /{ }_{10} \mathrm{KMnO}_{4}$ in terms of Fe ? $\mathrm{Fe}_{2} \mathrm{O}_{3}$ ? $\mathrm{Fe}_{3} \mathrm{O}_{4}$ ? $\mathrm{FeSO}_{4} 7 \mathrm{H}_{2} \mathrm{O}$ ?

$$
\text { Ans. } 0.00559,0.00799,0.007723,0.0278 \mathrm{I} .
$$

3. What is the strength of ${ }^{\mathrm{N}} / 10 \mathrm{KMnO}_{4}$ in terms of $\mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4}$ ? of CaO ? of $\mathrm{CaCO}_{3}$ ? of $\mathrm{CaSO}_{4}$ ?

Ans. 0.0045. 0.002805. 0.005005. 0.006808.
4. What is the strength of ${ }^{\mathrm{N}} /{ }_{10} \mathrm{KMnO}_{4}$ in terms of P and of $\mathrm{MoO}_{3}$ according to Noyes method?

$$
\text { Ans. } 0.000086 \mathrm{I} \text { and } 0.0048
$$

5. 1.5 grams of pig iron took 78 c.c. of ${ }^{\mathrm{N}} / 10 \mathrm{KMnO}_{4}$. What is the percentage of phosphorus?

$$
\text { Ans. } \quad 0.447 \%
$$

6. In determining iron in an ore, by mistake too much ${ }^{\mathrm{N}} /{ }_{10} \mathrm{~K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}$ was run in : the burette read 45 c.c.: 20 c.c. of $\mathrm{N} / 10 \mathrm{FeSO}_{4}$ were added and the titration finished : the burette then read 57 c.c. How much dichromate was required for the iron ore? Ans. 37 c.c.
7. Given a solution of $\mathrm{KMnO}_{4}$ i c.c. $=0.00559$ gram of iron. What is its strength in terms of manganese by the Volhard method and by the Ford-Williams method?

$$
\text { Ans. } \quad\left\{\begin{array}{l}
\text { Volhard i c.c. }=0.00165 \text { gram. }  \tag{87}\\
\text { Ford-Williams i c.c. }=0.00275 \text { gram. }
\end{array}\right.
$$

8. The $\mathrm{MnO}_{2}$ from one gram of spiegel was dissolved in 1.5 grams of ferrous ammonium sulphate, $\left(\mathrm{NH}_{4}\right)_{2} \mathrm{SO}_{4}, \mathrm{FeSO}_{4}, 6 \mathrm{H}_{2} \mathrm{O}$, and then titrated by ${ }^{\mathrm{N}} / 10$ $\mathrm{KMnO}_{4}: 2.05$ c.c. were used. What is the percentage of manganese?

Ans. 9.95\%.
9. 3 grams of steel required $60 \mathrm{c} . c$. of ${ }^{\mathrm{N}} /{ }_{10} \mathrm{KMnO}_{4}$ to oxidize the molybdenum, from the ammonium phosphomolybdate precipitate, from $\mathrm{Mo}_{24} \mathrm{O}_{37}$ to $\mathrm{MoO}_{3}$. What is the percentage of phosphorus? Ans. .177\%
10. A solution of $\mathrm{Na}_{2} \mathrm{~S}_{2} \mathrm{O}_{3}$ was made containing about 40 grams of the crystallized salt per liter ; this was standardized by portions of copper 0.200 gram each; they required 19.6 c.c. : 0.50 gram of a copper matte took 37.6 c.c. What is the percentage of copper?

$$
\text { Ans. } 76.73 \%
$$

II. Calculate the number of grams per liter to give half normal solutions of I, of $\mathrm{Na}_{2} \mathrm{~S}_{2} \mathrm{O}_{3}, 5 \mathrm{H}_{2} \mathrm{O}$, and of $\mathrm{SO}_{2}$.

Ans. I, 63.425 grams; $\mathrm{Na}_{2} \mathrm{~S}_{2} \mathrm{O}_{3}, 5 \mathrm{H}_{2} \mathrm{O}$, I 24.15 grams; $\mathrm{SO}_{2}, 16.015$ grams.
12. What is the strength of a $\mathrm{N} /{ }_{10}$ sodium thiosulphate solution in terms of iodine? of copper?

$$
\text { Ans. 0.012685. } 0.00636 .
$$

I3. What is the strength of $\mathrm{a}^{\mathrm{N}} / 5$ iodine solution in terms of $\mathrm{SO}_{2}$ ? $\mathrm{H}_{2} \mathrm{SO}_{3}$ ? $\mathrm{Na}_{2} \mathrm{SO}_{3}$ ?
Ans. 0.006406. 0.008208. 0.0126I6.
14. How many c.c. of ${ }^{\mathrm{N}} / 5 \mathrm{Na}_{2} \mathrm{~S}_{2} \mathrm{O}_{3}$ solution will be required to react with the iodine liberated by 20 c.c. of a ${ }^{\mathrm{N}} /{ }_{10} \mathrm{~K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}$ solution? Ans. Io c.c.
15. How many grams of copper will give when precipitated by potassium iodide sufficient iodine to require 20 c.c. of $\mathrm{N} /{ }_{10} \mathrm{SO}_{2}$ solution? How many for 10 c.c. of ${ }^{\mathrm{N}} /{ }_{10} \mathrm{Na}_{2} \mathrm{~S}_{2} \mathrm{O}_{3}$ solution? Ans. 0.1272 and 0.0636.
16. Five grams of pig iron took 12 c.c. of ${ }^{N} / 100$ iodine solution. What is the percentage of sulphur?

$$
\text { Ans. } 0.0384 \%
$$

17. In one gram of an antimony alloy, the antimony was determined by ${ }^{\mathrm{N}} /{ }_{10} \mathrm{Na}_{2} \mathrm{~S}_{2} \mathrm{O}_{3}, 24.2$ c.c. were required. What is the percentage of antimony? Ans. $14.54 \%$.
18. What amount of type metal must be taken for analysis so that the burette shall read percentage of antimony when ${ }^{\mathrm{N}} / 10 \mathrm{Na}_{2} \mathrm{~S}_{2} \mathrm{O}_{3}$ is used ?

$$
\text { Ans. } 0.601 \text { gram. }
$$

19. Five grams of bleaching powder were mixed in a mortar with water and diluted to one liter: 50 c.c. of this required 30 c.c. of ${ }^{N} /{ }_{10} \mathrm{Na}_{3} \mathrm{AsO}_{3}$ solution. What is the percentage of available chlorine? The reaction is $\mathrm{CaCl}_{2} \mathrm{O}+\mathrm{Na}_{3} \mathrm{AsO}_{3}=\mathrm{CaCl}_{2}+\mathrm{Na}_{3} \mathrm{AsO}_{4}$.

$$
\text { Ans. } \quad 42.54 \%
$$

20. Under the conditions of the preceding example what fraction of normal will read percentage direct?

$$
\text { Ans. } \frac{\mathrm{N}}{14.18}
$$

21. To 50 c.c. of a solution of chlorine an excess of potassium iodide was added; the liberated iodine was then estimated by a ${ }^{-1} / 10$ solution of $\mathrm{Na}_{2} \mathrm{~S}_{2} \mathrm{O}_{3}$ using starch as an indicator; 22.5 c.c. of $\mathrm{Na}_{2} \mathrm{~S}_{2} \mathrm{O}_{3}$ solution were used. What is the strength of the chlorine solution?

$$
\text { Ans. } 0.001595 \text { gram per c.c. }
$$

22. Five grams of pig iron were treated with hydrochloric acid and the $\mathrm{H}_{2} \mathrm{~S}$ evolved passed into 50 c.c. of ${ }^{\kappa} /{ }_{10} \quad \mathrm{Na}_{3} \mathrm{AsO}_{3}$ solution: the arsenious sulphide was filtered and washed, and the filtrate titrated with $\mathrm{N} / 10$ iodine, requiring 35 c.c. What was the percentage of sulphur in the sample? Ans. $0.721 \%$.
23. In titratıng 0.5 gram of an iron ore by $\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}$ the end point was passed when 60 c.c. of ${ }^{\mathrm{N}} / 10$ solution were used. One gram of Mohr's salt was added and the titration continued using 6.5 c.c. more. What was the percentage of iron? Ans. $45.84 \%$.
24. How much water must be added to 2 liters of stannous chloride solution containing 15 grams of tin per liter to make it equivalent to a $\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}$ solution which reads percentage of iron directly when 0.5 of a gram is taken for analysis?

Ans. 3637 c.c.
25. To 50 c.c. of a stannous chloride solution two grams of iron were added, as ferric chloride, the solution was then titrated by ${ }^{\mathbb{N}} /{ }_{10} \mathrm{KMnO}_{4} 35$ c.c. being required. How much $\mathrm{SnCl}_{2}$ per c.c. did the solution contain?

Ans. 0.006646 gram.

## CHAPTER VII.

## CALCULATIONS OF DENSITY OF SOLIDS AND LIQUIDS.

## DENSITY OF SOLIDS.

The density of solids and liquids is compared with that of water at the temperature of maximum density. The ratio of the density to that of water is the specific gravity. So if we say a substance has a specific gravity of 2.5 , we mean that a given volume has 2.5 times the weight of the same volume of water at $4^{\circ} \mathrm{C}$; or that its density relative to that of water is as 2.5 is to 1 .

The density of solids can be determined by the following methods. The usual classification is given here but no formulae, as these are more confusing than helpful and do not lead to a thorough understanding of the subject.
A. Solids heavier than water and insoluble.
(I) Weigh in air and then in water.

According to the law of Archimedes, a body immersed in a fluid loses a part of its weight equal to that of the fluid it displaces. So the weight of the solid in air minus its weight in water gives the weight of an equal volume of water; as the volume of water displaced is equal to that of the object, unless it is porous, when it must be allowed to soak in water for some time to expel the air. So if we divide the weight in air by the loss in weight in water, we have the specific gravity or density compared to that of water at the temperature at which the experiment was carried out. This can then
if necessary be corrected for the expansion of water and the true specific gravity compared to water at $4^{\circ} \mathrm{C}$ obtained. For great accuracy the weight in air should be reduced to weight in vacuo.

For example:- Suppose we have a piece of brass whose weight in air is 24.076 grams and in water 21.2436 grams. The weight in air divided by the loss in weight, 2.8324 grams, gives the specific gravity, 8.5, referred to that of water at the temperature of the experiment.
(2) If the substance is in small pieces or is a powder the following method is used:
(a) Weigh the substance in air.
(b) Weigh a small flask filled either entirely with water or to a certain mark.
(c) Place the substance in the flask, remove air, if necessary, by boiling and weigh with the water at the same point as before (either filled or to the mark).

It is evident that a volume of water equal to that of the substance has been displaced: to get the weight of this volume of water; weight of substance (a) + weight of flask and water (b) - weight of substance in flask and water (c) = weight of water displaced. Then weight of substance in air divided by the weight of an equal volume of water gives specific gravity. For example:

Weight of powder, 7 grams.
Weight of flask and water (to mark) 55 grams.
Weight of flask, powder and water (to mark) 59 grams.

We have $55+7-59=3$ weight of volume of water displaced by powder : and $\frac{7}{3}=2.333$, the specific gravity of the powder.

By having graduations on the neck of the flask, the volume of the substance may be read off by the rise of the water in the flask, then this volume in c.c. multiplied by the weight of 1 c.c. of water at the temperature, gives the weight of an equal volume of water.
B. Solids lighter than water and insoluble.

As these solids are lighter, they cannot be weighed in water without a sinker.

The data necessary is-
Weight of substance in air.
Weight of sinker in water.
Weight of substance and sinker in water.
Or if we have the weight of sinker in air and its specific gravity we can calculate the weight of the sinker in water.

As the substance is lighter than water, the weight of sinker and substance in water is less than the sinker alone.

If we subtract from weight of sinker and substance in water the weight of sinker in water, we have the weight of substance in water, a negative quantity and the measure of its buoyant power.

Now the weight in air divided by the weight in air minus the weight in water is the specific gravity, but the weight in air minus the negative weight in water equals the weight in air plus the buoyant power, so we have in this case the specific gravity is equal to the weight in air divided by the weight in air plus the difference in weights of the sinker in water and the substance and sinker in water.

To illustrate by an example.-
Weight of substance in air 4 grams.
Weight of sinker in water 9 grams.

Weight of substance and sinker in water 8 grams.
Difference in weight of sinker in water and substance and sinker in water is one gram: weight in air plus this difference (or minus the negative loss in weight of one gram) is 5 .
$\frac{4}{5}=0.8$ the specific gravity of the substance.
If we have the weight of the sinker in air and its specific gravity.

The weight in air divided by the specific gravity gives the volume, or expressed in grams, the weight of an equal volume of water. This is equal to the loss of weight in water.

The weight in air minus the loss of weight in water gives the weight in water.

For example, suppose the sinker weighed 12 grams and its specific gravity was 8 .
$\frac{12}{8}=1.5$ (loss in weight) and I2-1.5 or $10.5=$ weight of sinker in water.

C Solids heavier than water but soluble.
Weigh in air then in a liquid of known specific gravity in which the substance is insoluble, such as turpentine, petroleum, alcohol, \&c.

The weight in air divided by the loss in weight gives the density relative to the liquid used; suppose this is 7 and the specific gravity of the liquid 0.8 , to find the specific gravity we have

$$
7: x:: 1: 0.8 \text { or } 7 \times 0.8=5.6 \mathrm{Sp} . \mathrm{Gr} .
$$

Or, the loss in weight of the solid equals the weight of liquid displaced. Let this be $x$ and $y$ the weight of the same volume of water; then $x: y:: 0.8: 1$ and the weight in air divided by $y$ gives the specific gravity.

To determine the specific gravity of rock salt. Given :
Weight of sample in air 10.436 grams
Weight of sample in turpentine 6.3547 grams
Specific gravity of turpentine 0.86
$10.436-6.3547=4.08 \mathrm{r} 3$ loss in weight in turpentine equal to the weight of an equal volume of turpentine.

Let $y=$ weight of an equal volume of water $4.0813: y:: 0.86:$ I. $y=4.7457$ and $\frac{10.4360}{4.7457}=2.199 \mathrm{Sp}$. Gr. of rock salt.
or $\frac{10.436}{4.0813}=2.5572$ density relative to turpentine and
2.5572 : x : : $\mathrm{I}: 0.86$. $\mathrm{x}=2.199 \mathrm{Sp}$. Gr. of rock salt.
D. Solid lighter than water and soluble.

Weigh with a sinker in some liquid which does not act on the substance and calculate the density relative to the liquid; then from the specific gravity of the liquid calculate the specific gravity as under $C$.

To determine the specific gravity of lithium-
Weight of lithium in air 3. grams
Weight of sinker in air 10. grams
Weight of lithium and sinker in kerosene 7.9222 grams.

Specific gravity of sinker (silver) 10.5
Specific gravity of kerosene used 0.829
First find the specific gravity of the sinker referred to kerosene

$$
0.829: 1:: 10.50: x . \quad x=12.6658
$$

Next find the weight of the sinker in kerosene we have

$$
\frac{10}{10-y}=12.6658 . \quad y=9.2104
$$

Now following the method for solids lighter than water and insoluble

$$
\frac{3}{3+9.2104-7.9222}=0.6996 \text { density of lithium }
$$

relative to kerosene : and to refer to water we have,

$$
0.829: 1:: z: 0.6996 . \quad z=0.57996
$$

The specific gravity of lithium is therefore 0.58 .
In these examples no particular attention has been given to the temperature of the water, but the specific gravity has simply been referred to water at the same temperature (that of the experiment). To refer these specific gravities to water at $4^{\circ} \mathrm{C}$; look up in the table, at the back of the book, the weight of a cubic centimeter of water at the particular temperature used, then substitute in the proportion, Sp. Gr. $x^{\circ} \mathrm{C}$ : Sp. Gr. $4^{\circ} \mathrm{C}$ : : i : wt. I c.c. water at $x^{\circ} \mathrm{C}$. *

This is the same proportion used for the conversion of the relative density of a solid in turpentine to density referred to water (specific gravity) and it is a similar proposition; for water at say $20^{\circ} \mathrm{C}$ is a liquid lighter than water at $4^{\circ} \mathrm{C}$ so the specific gravity referred to water at $4{ }^{\circ} \mathrm{C}$ will necessarily be less.

The correction for the weight of the solid in air is too small to have significance here and will be discussed in the next chapter.

## DENSITY OF LIQUIDS.

The specific gravity of liquids is determined as follows:
ist. By the pyknometer or specific gravity bottle.

[^6]2d. By weighing a solid of known specific gravity in the liquid.

3d. By hydrometers.
4th. By Westphal's balance. This is really only a modification of the second method.
ist. In the pyknometer we can compare directly the weights of the same volume of the liquid and of water ; so that the calculation only involves the subtraction of the weight of the pyknometer and the division of the weight of the liquid by that of an equal volume of water.

2d If we have, for example, a piece of brass, which weighs in air 10 grams, in water 8.824 grams and in the liquid of unknown specific gravity 9 grams: we have in each case the loss of weight of the brass equals the weight of the volume of liquid displaced; and, as the volume is the same in both cases, the loss in weight is directly proportional to the specific gravity and we have
1.176 : $\quad$ : : $\quad$ : $\quad x . \quad x=0.85$ Loss of wt. Loss of wt. Sp. Gr. of Sp. Gr. of in water. in Liquid. water. liquid.

Or if we know the weight of the brass in air and its specific gravity we can calculate the loss of weight in water as already explained under the density of solids.

3d Hydrometers are made either to read specific gravity direct, like the lactometer, or are graduated according to some arbitrary scale of degrees.

Degrees Beaumé and specific gravity may be compared by reference to the tables at the end of the book.

Degrees Twaddell have a direct relation to specific gravity. $200^{\circ}$ represent the densities between I and 2 so $I^{\circ}$ represents a difference of specific gravity of 0.005 ,
hence the specific gravity is $\mathrm{I}+\frac{\mathrm{N}^{\circ} \text { (Twaddell) }}{200}$.
$36^{\circ}$ Twaddell is 1.18 Sp . Gr.
$94^{\circ}$ Twaddell is 1.47 Sp . Gr. and so on.
4th. In using the Westphal's balance each weight gives the figure for a decimal place beginning with the largest. If the liquid is heavier than water a weight (largest size) must be placed on the hook to help sink the float. This weight gives I (before the decimal point) and the remaining weights the decimals.

Under the specific gravity of liquids come the problems of dilution to a certain specific gravity. This can of course be done without any calculation by the use of a hydrometer. The following method will however be found useful, although not strictly accurate on account of a small contraction of volume on mixing which is found by very accurate measurements. *

Suppose we wish to make 200 c.c. of ammonia water 0.96 Sp . Gr. and we have, ammonia water 0.88 Sp . Gr. and water. The ratio is inversely as the difference in specific gravities . $08(.96-.88)^{\ominus}$ : . $04(1.00-.96)^{\ominus}$ : : volume of water : volume of ammonia $=$ two parts of water to one of strong ammonia, or 66.66 cc. diluted to 200.

Required to make six liters of nitric acid I. 26 Sp. Gr. having nitric acid 1.42 Sp. Gr. and water.

26: 16 : : volume of acid : volume of water: or 16 parts of water for $4^{2}$ of diluted acid : for 6 liters, $16: 4^{2}$ $:: x: 6 . \quad x=2.285$. Or, let $y=$ volume of nitric acid in liters $1.42 \mathrm{y}+6-\mathrm{y}=6$ (1.26). $\quad \mathrm{y}=3.7 \mathrm{I} 4$.

These methods can be applied to any case of mixing, as the contraction previously mentioned will not introduce any error appreciable in ordinary work.
 $2+1=3=$ vol. of solution

$$
\begin{aligned}
3: 200 & =1: x \\
x & =66.660
\end{aligned}
$$

Suppose we wish to make up two liters of a standard sulphuric acid solution containing ten grams of $\mathrm{H}_{2} \mathrm{SO}_{4}$ per liter. Dilute pure concentrated sulphuric acid with water to about 1.7 Sp . Gr. allow to cool to $15^{\circ} \mathrm{C}$ and then take the specific gravity most accurately, suppose it to be 1.689. The percentage of $\mathrm{H}_{2} \mathrm{SO}_{4}$ can be found by referring to a table* to be 76.29. The weight of sulphuric acid to be diluted will be $\frac{10 \times 2 \times 100}{76.29}$
$=26.2 \mathrm{I} 57$ grams. This when diluted with water to two liters at $15^{\circ} \mathrm{C}$ will give a solution containing ten grams of $\mathrm{H}_{2} \mathrm{SO}_{4}$ per liter. In this calculation the specific gravity is referred to water at $15^{\circ} \mathrm{C}$ as unity, this is to agree with the liter used in dilution (volume of 1000 grams of water at $15^{\circ} \mathrm{C}$ ). Should we wish to compare this with other specific gravities it can be reduced to specific gravity at $4^{\circ} \mathrm{C}$ as already explained.

This brings us to the consideration of changes in specific gravity due to temperature.

With solids the change in volume is so small that no appreciable error is introduced by neglecting this variation within the limits of laboratory temperature.

With liquids the variations of specific gravity due to changes in temperature are greater and cannot be disregarded. Unless specially stated the specific gravity is referred to water it $4^{\circ} \mathrm{C}$ as unity and for accurate work the determination must be carried out at that temperature. For many important solutions and liquids the corrections for temperature have been worked out and are to be found in the books on technical chemistry.

[^7]Thorpe's Dictionary of Applied Chemistry gives the following variations of sulphuric acid

| $0^{\circ} \mathrm{C}$ | $10^{\circ} \mathrm{C}$ | $20^{\circ} \mathrm{C}$ | $30^{\circ} \mathrm{C}$ | $40^{\circ} \mathrm{C}$ | $50^{\circ} \mathrm{C}$ |
| :--- | :--- | :--- | :--- | :--- | :--- |
| 1.857 | 1.846 | 1.835 | 1.825 | 1.816 | 1. 806 |

In many cases the correction is given for $\mathrm{I}^{\circ} \mathrm{C}$ over a range of temperatures: these are added to the specific gravity at the temperature of the experiment to obtain the gravity at $4^{\circ}$ C.*

## VOLUME OCCUPIED BY PRECIPITATES.

In analyses such as that of pig lead for bismuth, the question of the volume occupied by a precipitate becomes of importance.

Suppose seventy-five grams of impure lead is dissolved in nitric acid, the lead precipitated by sulphuric acid, diluted to one liter and thoroughly mixed. To save time in filtering and washing, it is desired to draw off for the determination of bismuth, such a volume of the solution as shall represent fifty grams of the original sample.

Two-thirds of (IOOO c.c. minus the volume of the precipitate) will be the volume required. The amount of impurities is small and the solubility of lead sulphate will not introduce an appreciable error, so we assume that the weight of lead sulphate will be proportional to the seventy-five grams of pig lead.

$$
75: x:: 206.9: 302.96 . \quad x=109.82 \text { grams. }
$$

The specific gravity of $\mathrm{PbSO}_{4}$ is 6.2 therefore the volume occupied by the precipitate is $\frac{109.82}{6.2}$ or 17.7 c.c. So to

[^8]get a solution containing the bismuth from fifty grams of pig lead, we must draw off or filter through a dry filter $\frac{2}{3}(1000-17.7)$ or 654.86 c.c.

If we have a solution containing a precipitate and wish to titrate the excess of precipitant in a portion of the solution, we dilute to the mark in a flask, mix, and then draw off a portion with a pipette. Suppose the solution is diluted to 200 c.c. and 50 c.c. withdrawn; this is evidently more than one quarter on account of the volume occupied by the precipitate. This error is usually disregarded, but it can be found as follows. If we have precipitated the lead from one gram of lead ore as $\mathrm{PbCrO}_{4}$, by a known amount of $\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}$, and wish to determine the excess by titration with potassium iodide and sodium thiosulphate in a portion of the filtrate; instead of filtering, washing and then diluting to a known volume we may proceed as follows: after adding $\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}$ in excess, dilute to 200 c.c. mix thoroughly and allow the precipitate to settle; then withdraw 50 c.c. of the clear solution and titrate the excess with sodium thiosulphate after adding potassium iodide and hydrochloric acid. This shows, we will assume, an excess of 100 mgs . of $\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}$; on the assumption that we have titrated one quarter of the solution, the total excess of $\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}$ will be 400 mgs . This is subtracted from the known weight of $\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}$ added and the lead present calculated from the remainder in the usual way, giving say $80 \%$ of lead.

Now that we have determined approximately the lead present, we can from this calculate the volume occupied by the lead chromate and so correct this percentage of lead for the volume occupied by the precipitate. $80 \%$ $\mathrm{Pb}=0.8$ gram Pb in one gram $=1.249$ grams $\mathrm{PbCrO}_{4}$.

The specific gravity of $\mathrm{PbCrO}_{4}$ is 6 , hence the volume occupied by the precipitate is $\frac{1.249}{6}$ or 0.21 c.c. 50 c.c: showed an excess of 100 mgs . of $\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}$, to get the correct total excess, we have-50:200-0.21:: $100: x$. $x=399.58 \mathrm{mgs}$. or 0.42 milligram more $\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}$ was used in precipitating $\mathrm{PbCrO}_{4}$ than was found before. Which is equivalent to 0.59 milligram of lead, so that the correct weight of lead present was 0.80059 gram, equivalent to $80.059 \%$.

It will be observed that this correction depends mainly on two things-the excess of reagent and the dilution. If the excess is small and the dilution considerable, the error due to the volume of the precipitate can be neglected.

The accuracy of this method of calculating the volume of the precipitate is questioned by Ostwald, on account of the variation of the specific gravity of the precipitate in the solution, due mainly to adsorption. The method however is much used in commercial analytical work with satisfactory results.

## EXAMPLES.

1. A piece of barite (heavy spar) weighs in air 47 grams and in water 36.555 grams. What is its specific gravity?

Ans. 4.5 .
2. A specimen of magnetite weighed in air 27 grams and in water 21.60 grams. What is its specific gravity? Ans. 5.
3. A piece of loaf sugar weighed in air 7.5 grams and in petroleum ether, Sp. Gr. 0.645, 4.4635 grams. What is its specific gravity? Ans. I.593.
4. A sample of magnetic sand weighed in air 12 grams. A flask filled with water to a mark weighed 47.5327 grams. The same flask containing the sand and filled to the same mark with water weighed 56.428 I grams. What is the specific gravity of the sand ?

$$
\text { Ans. } 3.864
$$

5. To find the specific gravity of a piece of freshly cut pine wood. Given :
Weight in air, . . . . 10.100 grams Weight of sinker in water, . . 12.24 grams Weight of wood and sinker in water, 11.217 grams Ans. 0.908.
6. To find the specific gravity of common salt, given the following data:
Weight of salt in air, . . . 8.8450 grams Weight of flask and turpentine to mark, 45.2375 grams (103)

Wt. of flask, salt and turpentine to mark, 50.5609 grams Specific gravity of turpentine, 0.86

$$
\text { Ans. } 2.16
$$

7. To find the specific gravity of metallic sodium. Given :
Weight in dry air, . . . 14.15629 grams
Weight in kerosene, . . . 2.1807 grams
Specific gravity of kerosene, . . . 0.829 Ans. 0.98.
8. To find the specific gravity of turpentine. Given: Weight of pyknometer, . . . 25.0456 grams Wt. of pyknometer filled with water, • 72.1485 grams Wt. of pyknometer filled with turpentine, 65.5541 grams Ans. 0.86 .
9. A piece of silver weighed 47 grams in water and 48.756 grams in petroleum ether, specific gravity 0.645 . What is the specific gravity of the silver?

$$
\text { Ans. } \quad 10.5 .
$$

10. A ten gram brass weight, Sp. Gr. 8.5, weighed in glycerin $8.5^{1} 35$ grams. What is the specific gravity of glycerin? Ans. 1.2635.
II. Given the specific gravity of sulphuric acid as r. 84 compared to water at $15^{\circ} \mathrm{C}$. What is its specific gravity compared to water at $4^{\circ} \mathrm{C}$ ? (See tables.)

Ans. 1.8384.
12. Given the specific gravity of alcohol at $20^{\circ} \mathrm{C}$ referred to water at $4^{\circ} \mathrm{C}$ as $0.833^{2}$. What is its specific gravity referred to water at $20^{\circ} \mathrm{C}$ ? Ans. 0.83467 .
13. How much phosphoric acid, 1.7 Sp. Gr. and how much water are required to make 400 c.c. of i.I8 Sp. Gr. ?

Ans. 102.85 c.c. phosphoric acid and 297.15 c.c. of water.
14. How much nitric acid I .47 Sp . Gr. and water must be mixed to give three liters of 1.08 Sp . Gr. ?

Ans. 510.6 c.c. nitric acid; 2489.4 c.c. water.
15. How much ammonia water 0.9 Sp . Gr. must be taken to make with water four liters 0.96 Sp . Gr.?

Ans. 1.6 liters.
16. We have two liters of dilute sulphuric acid m .08 Sp. Gr., which we wish to use up in diluting concentrated sulphuric acid 1.82 to 1.20 Sp . Gr. How much concentrated acid is to be added? Ans. 387.1 c.c.

17 What is the volume occupied by 47 grams of $\mathrm{PbSO}_{4}$. Sp. Gr. 6.2 ? Ans. 7.5 c.c.
18. How many c.c. of sulphuric acid, i. 824 Sp. Gr. compared to water at $15^{\circ} \mathrm{C}$, weigh 100 grams? Ans. 54.88 c.c.
19. What is the volume occupied by the barium sulphate from one gram of $\mathrm{FeS}_{2}$ ? Sp. Gr. $\mathrm{BaSO}_{4} 4.5$.

$$
\text { Ans. } \quad 0.86 \text { c.c. }
$$

20. To two grams of a mineral containing barium, 200 mgs. of $\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}$ were added to precipitate the barium and the solution diluted to 500 c.c., mixed and allowed to settle: $50 \mathrm{c} . \mathrm{c}$. of the clear solution was titrated for the excess of $\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}$ by KI and $\mathrm{Na}_{2} \mathrm{~S}_{2} \mathrm{O}_{3}$ showing 4.2 mgs . What is the corrected percentage of barium oxide? Given the Sp. Gr. of $\mathrm{BaCrO}_{4}$ as 3.9.

Ans. 8.23\%. Showing the correction to be insignificant.

## CHAPTER VIII.

## CALCULATIONS OF GASES.

Before proceeding to any of the calculations of gases or gas analysis a knowledge of the following laws is necessary.

Law of Boyle or Mariotte.
i. The temperature remaining the same, the volume of a given quantity of gas is inversely as the pressure it bears.

Law of Charles or Gay-Lussac.
2. The coefficient of expansion of all gases is 0.00366 or $\frac{1}{273}$ of the volume at $o^{\circ} \mathrm{C}$.

Differently expressed, the volume of all gases is directly proportional to the temperature calculated from the absolute zero $\left(-273^{\circ} \mathrm{C}\right)$.

Law of Avogadro.
3. Under the same temperature and pressure equal volumes of all gases contain the same number of molecules.

It is evident from (I) and (2) that the volume of gases varies greatly under different conditions of temperature and pressure so that these must always be reduced to the standard conditions of $0^{\circ} \mathrm{C}$ and 760 milli-. meters pressure for comparison.

This is done as follows: Suppose we have six liters of a gas at $18^{\circ} \mathrm{C}$. and $772 \mathrm{~m} . \mathrm{m}$. pressure and we wish to know the volume under the standard conditions. We can first correct for temperature and then for pressure or vice versa. The volume varies as the temperature calculated from the absolute zero, therefore

$$
273: 273+18:: x: 6 . \quad x=5.6288 .
$$

The volume at $0^{\circ} \mathrm{C}$ and $772 \mathrm{~m} . \mathrm{m}$. is 5.6288 liters. The volume varies inversely as the pressure, therefore:
$772: 760:: y: 5.6288 . \quad y=5.7176$ liters, the volume of the gas at $0^{\circ} \mathrm{C}$ and $760 \mathrm{~m} . \mathrm{m}$. pressure.

These calculations are necessary in gas analysis and in many other analytical determinations where the volume of a gas is measured. When the gas is measured over water it contains aqueous vapor which supports part of the pressure: this tension increases with the temperature (see table), therefore before proceeding to the corrections for temperature and pressure as before, the tension of aqueous vapor must be subtracted from the barometer reading to get the real pressure supported by the gas. Take the following example of a nitrogen combustion. Weight substance 0.1923 gram : volume nitrogen 24.6 c.c.: temperature $25^{\circ} \mathrm{C}$. : barometric pressure $771 \mathrm{~m} . \mathrm{m}$. The tension of aqueous vapor at $25^{\circ} \mathrm{C}$ is $23.5 \mathrm{~m} . \mathrm{m}$.; so $77 \mathrm{I}-23.5$ or $747.5 \mathrm{~m} . \mathrm{m}$. is the pressure supported by the nitrogen. As the volume varies inversely as the pressure, we have:

$$
24.6: x:: 760: 747.5 . \quad x=23.93 \text { c.c. }
$$

(volume at normal pressure)
As volume varies directly as the temperature calculated from the absolute zero.

$$
23.93: y:: 273+25: 273 . \quad y=21.95 \text { c.c. }
$$

volume of nitrogen at standard conditions. I c.c. nitrogen at $760 \mathrm{~m} . \mathrm{m}$. and $0^{\circ} \mathrm{C}$ weighs 0.001254 gram (see table).
Wt. of nitrogen is $0.001254 \times 21.95=0.02751$ gram and $\frac{0.0275}{0.1923} \times 100=14.31 \%$ nitrogen.

Suppose we have 200 c.c. of gas at $10^{\circ} \mathrm{C}$ and 765 $\mathrm{m} . \mathrm{m}$. and wish to know the volume at $18^{\circ} \mathrm{C}$ and 772 m.m. : to correct for temperature, we have :
$200: x:: 273+10: 273+18 . x=202.08$ c.c. and for pressure

$$
202.08: y:: 772: 765 . \quad y=200.24 \text { c.c. }
$$

the volume under the desired conditions.

DENSITY OF GASES.
The density of gases is referred sometimes to air at $760 \mathrm{~m} . \mathrm{m}$. pressure and $0^{\circ} \mathrm{C}$. as unity and sometimes to hydrogen under the same conditions of temperature and pressure. In the actual determinations it is usually compared with an equal volume of air and then referred to hydrogen by calculation. Since a liter of hydrogen weighs 0.08973 gram under the standard conditions and a liter of air 1.29327 grams, the density referred to air can be referred to hydrogen by multiplying by 14.4 I .

The important relation between the molecular weight and density of gases referred to hydrogen has already been mentioned under the calculation of atomic weights, as a means of determining what multiple of the equivalent is the atomic weight ; it is also one of the most important methods for determining molecular weight. When
we say the density of a gas is 40 referred to hydrogen, it means that any given volume of the gas is 40 times as heavy as the same volume of hydrogen, under the same conditions of temperature and pressure. Now according to the law of Avogadro, these equal volumes of gases contain the same number of molecules so each molecule of the gas is 40 times as heavy as a molecule of hydrogen, and as the hydrogen molecule contains two atoms, a molecule of the gas is 80 times as heavy as a hydrogen atom or its molecular weight is 80 . Or, in brief, the density of a gas (referred to hydrogen) is one half its molecular weight.

The exact calculation of density and so molecular weight varies with the method used, but in general it is as follows:

We have given the weight of a known volume of gas under certain conditions of temperature and pressure. Reduce these to $0^{\circ} \mathrm{C}$ and 760 m . m., and divide the weight by that of an equal volume of hydrogen under the same conditions and we have the density. The density of vapors is determined in a similar way, except that the volume occupied by the vapor from a known weight of substance, is measured instead of the weight of a known volume of vapor or gas. In many cases, especially when the heat necessary to convert the substance into the gaseous condition is high, it is more convenient to measure the volume of air displaced by the substance in the gaseous form, rather than the gas itself; but the calculation is the same, for the volume occupied by the air is the same as would be occupied by the vapor from the known weight of the substance at the same temperature and pressure.

The gram-molecular volume is the volume in liters occupied by the molecular weight in grams of any substance in the gaseous state at $0^{\circ} \mathrm{C}$. and $760 \mathrm{~m} . \mathrm{m}$. pressure. Now according to the law of Avogadro equal volumes of all gases contain the same number of molecules or conversely an equal number of molecules occupy the same volume, so that the gram-molecular volume of all gases is the same. This is calculated as follows: the molecular weight of oxygen in grams is 32 : the weight of a liter of oxygen is I .429 grams: the grammolecular volume is therefore $32 \div 1.429$ or 22.393 liters.

So we may consider the molecular weight, as that weight of a substance in grams, which in the state of a gas at $0^{\circ} \mathrm{C}$. and $760 \mathrm{~m} . \mathrm{m}$. pressure occupies 22.393 liters, or in round numbers 22.4 liters; or dividing by one thousand, the weight in milligrams which occupies 22.4 cubic centimeters under these conditions.

This conception of molecular weight is not only important in itself but simplifies the calculation of the molecular weight determinations where volumes of gases are measured, as will be seen by the following examples, which are worked out by both methods.

The following determinations of the density of chloroform vapor by the three principal methods, illustrate these calculations.
(i) Dumas' method. Given the following data.-

Weight of bulb filled with air at $19^{\circ} \mathrm{C}$ and 763.9 $\mathrm{m} . \mathrm{m} .=36.4489$ grams .

Weight of bulb filled with vapor at $101{ }^{\circ} \mathrm{C}$ and 763.9 $\mathrm{m} . \mathrm{m} .=37.2085$ grams .

Volume of air in the bulb at $19^{\circ} \mathrm{C}=279$ c.c.

First find the weight of the air contained in the bulb; by reducing the volume to the standard conditions and multiplying by 0.001293 , the weight of I c.c. of air at $0^{\circ} \mathrm{C}$ and 760 m . m.

$$
\begin{array}{rrrr}
279: x:: 273+19: 273 . & x=260.8 \text { c.c. } \\
260.8: y:: 760 & : 763.9 . & y=262.1 \text { c.c. }
\end{array}
$$

Weight of air is $262.1 \times 0.001293=0.3389$ gram .
Weight of bulb is $36.4489-0.3389=36.1$ Io0 grams.
Weight of vapor is $37.2085-36.1100=1.0985$ grams.
We now know that 279 c.c. of chloroform vapor at IOI ${ }^{\circ} \mathrm{C}$ and 763.9 m . m. weighed I .0985 grams.

To find the corresponding volume under the standard conditions, we have :

$$
\begin{aligned}
279: x:: 273+101: 273 . \quad x=203.8 \text { c.c. } \\
203.8: y:: 760: 763.9 \quad y=204.8 \text { c.c. }
\end{aligned}
$$

The weight of an equal volume of air will be

$$
204.8 \times 0.001293 \text { or } 0.2648 \text { gram. }
$$

So

$$
1.0985 \div 0.2648 \text { or } 4.148
$$

is the density referred to air:

$$
4.148 \times 14.4 \mathrm{I} \text { or } 59.773
$$

is the density referred to hydrogen and

$$
59.773 \times 2 \text { or } 119.546
$$

is the molecular weight. Theory in9.36. Or 1.0985 grams occupy 204.8 c.c. The molecular weight will occupy 22.4 liters. Hence

$$
1.0985: x:: 0.2048: 22.4 . \quad x=120.15
$$

(2) Victor Meyer's method. Given following data.

Weight of chloroform taken 0.2097 gram.
Volume of air expelled by vapor 43.65 c.c.
Temperature of air expelled $20^{\circ} \mathrm{C}$.
Height of barometer $763.9 \mathrm{~m} . \mathrm{m}$.
Tension of aqueous vapor at $20^{\circ} \mathrm{C}$ (from table) 17.36 m. m.

We have the volume of air expelled by and equal to the volume of the vapor; to find its weight reduce this volume to the standard conditions;

$$
\begin{aligned}
& 43.65: x:: 273+20: 273 . \quad x=40.67 \text { c.c. } \\
& 40.67: y:: 760: 763.9-17.36 . \quad y=38.50 \text { c.c. }
\end{aligned}
$$

$38.50 \times 0.001293=0.04978$ gram : weight of air.
Then $0.2097 \div 0.04978$ is 4.2 I , the density referred to air ;
4.2I $\times 14.4 \mathrm{I}=60.67$, the density referred to, hydrogen; $60.67 \times 2=121.34$, the molecular weight. Or as 0.2097 gram occupied 38.5 c.c. 0.2097 : $\mathrm{x}:$ : 0.0385 : 22.4. $\quad x=122.01$.
(3.) Hofmann's method. The following data are required:

Weight of chloroform O.I 535 gram.
Volume of vapor at $100^{\circ} \mathrm{C} 79 \mathrm{c.c}$.
Height of barometer at $2 \mathrm{I}^{\circ} \mathrm{C} 774.8 \mathrm{~m} . \mathrm{m}$.
Height of column of mercury (inside heating jacket) at $100^{\circ} \mathrm{C} 246.5 \mathrm{~m} . \mathrm{m}$.

Height of column of mercury (outside heating jacket) at $25^{\circ} \mathrm{C} 143.8 \mathrm{~m} . \mathrm{m}$.

* Tension of mercury vapor at $100^{\circ} \mathrm{C} 0.27 \mathrm{~m} . \mathrm{m}$.

This calculation involves, besides those already discussed, the reduction of the barometric readings to $0^{\circ} \mathrm{C}$; because they are at such widely varying temperatures. The coefficient of the expansion of mercury is 0.00018

[^9]for $I^{\circ} \mathrm{C}$ : so to reduce the reading representing the atmospheric pressure to zero, we have:
\[

$$
\begin{gathered}
\mathrm{I}: \mathrm{I}+(2 \mathrm{I} \times 0.000 \mathrm{I} 8):: \mathrm{x}: 774.8 \text { or } \\
774.8 \div \mathrm{I} .00378=77 \mathrm{I} .88 \mathrm{~m} . \mathrm{m} .
\end{gathered}
$$
\]

For the other columns of mercury we have :

$$
\begin{gathered}
246.5 \div 1.018=242.14 \mathrm{~m} . \mathrm{m} . \text { and } 143.8 \div 1.0045= \\
\text { 143.15 m. m. }
\end{gathered}
$$

The 79 c.c. of vapor is under the pressure indicated by the barometer minus the tension of mercury vapor ( $0.27 \mathrm{~m} . \mathrm{m}$. ) and minus the sum of the two columns of mercury also supported by the atmospheric pressure (242.14 +143.15 ). So the pressure is $771.88-(0.27$ $+242.14+143.15)=385.56 \mathrm{~m} . \mathrm{m}$.

We now know that 0.1535 gram of vapor at $100^{\circ} \mathrm{C}$ and 385.56 m . m. occupy 79 c.c. Reduce this as before to $0^{\circ} \mathrm{C}$ and $760 \mathrm{~m} . \mathrm{m}$. pressure and divide the weight by that of an equal volume of air:

$$
\begin{aligned}
& 79: x:: 373: 273 . \quad x=57.82 \mathrm{c} c . \\
& 57.82: y:: 760: 385.56 . \quad y=29.333 \text { c.c. } \\
& 29.333 \times 0.001293=0.037927 \\
& 0.1535 \div 0.037927=4.047 \text { the density re- }
\end{aligned}
$$

ferred to air.

## DENSITY BY EFFUSION.

The density or specific gravity of gases can be determined with sufficient accuracy for many practical purposes by the effusion test.*

This is based on the fact that the specific gravity of gases is proportional to the squares of the times of effusion. In these tests it is most convenient to determine

[^10]the specific gravity with reference to air and then, if necessary, refer it to hydrogen by calculation.

Suppose a certain volume of air requires twenty minutes to escape through an opening made by a needle in a platinum foil, and that under the same conditions of temperature and pressure the same volume of another gas requires twelve minutes.

Let $x=$ density of this gas : then
x : $1:$ : 144 : 400 . $x=0.36$, density referred to air, and $0.36 \times 14.41=5.188$, density referred to hydrogen.

This test is much used for illuminating gas at the works, but is not sufficiently accurate for scientific work.

## CORRECTION OF WEIGHINGS.

According to the law of Archimedes, when any object is weighed under the ordinary conditions in air, we obtain less than the true weight on account of the loss in weight of the object equal to that of the air displaced. This correction is small, but it must be made in some cases, especially when large light apparatus is weighed, such as absorption bulbs \&c., and in all very accurate determinations, such as atomic weights.

The correction is therefore the addition of the weight of an equal volume of air at the temperature of the weighing. This may be done as follows: weight in air then in water; the loss in weight is equal to the weight of the same volume of water; now, at the ordinary laboratory temperature the density of air referred to water as unity is 0.0012 , so the loss in weight of the substance in water times $0.0012^{*}$ is the correction to add.

[^11]If the specific gravity of the object is known the correction can be calculated as follows:
$\frac{\text { Wt. in air }{ }^{*}}{\text { Sp. Gr. }}=$ volume in c.c.
Volume times weight of Ic.c. of air (0.0012) is the correction to add.

In making corrections for weighing it must be borne in mind that we have:
(a) The apparent weight, that actually found.
(b) The true weight in vacuo, obtained by calculation.

To get the true weight of any object, we must add to its apparent weight the weight of an equal volume of air and subtract the weight of a volume of air equal to that of the weights used. The correction for the weights diminishes the correction for substances having a lower specific gravity than that of the weights; when the densities are the same the corrections equalize each other: when the density of the object is greater than that of the weights the correction becomes negative (is to be subtracted).

Suppose we have a 100 gram brass weight correct in air; it will weigh slightly more in vacuo. To find this weight we have:
True weight $=$ apparent weight $+\frac{(\text { true wt. } \times 0.0012)}{\text { Sp. Gr. }}$ or $\frac{100}{8.5} \times-0.0012=0.0141$; so that the true weight in vacuo is 100.0141 grams.

Let us use this weight to weigh different substances and calculate their true weight.

[^12]1st. Sulphur, specific gravity 2. The correction will be volume $\times 0.0012$ or $\frac{100}{2} \times 0.0012=0.06$ so that the true weight becomes

$$
100+(0.06-0.0141)=100.0459
$$

We see from this that the true weight is that of the brass weight in air plus the weight of air displaced by the object less that displaced by the weight itself.

2nd. If we balance the 100 gram brass weight with brass of the same specific gravity, we shall have the correction to add $\frac{100}{8.5} \times 0.0012=0.014$ and that to deduct o.or4, so that the true weight coincides with the apparent weight.

3 rd . If we balance the 100 gram brass weight with platinum, specific gravity 21.5 , we shall find the true weight less than 100 grams; for the correction to add is $\frac{100}{21.5} \times 0.0012=0.0056$; while that to subtract is as before 0.014: hence the true weight becomes $100+0.0056$ $-0.014=99.9916$ grams.

It will be seen from the preceding that the correction is different for brass and for platinum weights, and that the correction becomes greater as the specific gravity become less.

Suppose we have a glass vessel whose apparent weight is 75 grams when weighed with brass weights, and whose specific gravity is 2.5 . What is the true weight?

The volume is $\frac{75}{2.5}$ or 30. c.c.; the weight of an equal volume of air is $30 \times 0.0012=0.036$ gram: the correction for the brass weights is $\frac{75}{8.5} \times 0.0012=0.0105$
gram : so the true weight becomes $75+(0.036-0.0105)$ $=75.0255$ grams.

The following table gives the weight in milligrams to be added or subtracted for each gram of apparent weight of substance, for different specific gravities, when weighed in air with brass weights.*

| Sp. Gr. | Correction. | Sp. Gr. | Correction. | Sp. Gr. | Correction. |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 0.7 | +1.57 | 2.0 | +0.458 | 9. | -0.009 |

## CALCULATIONS OF GAS ANALYSIS.

With the help of the law of Avogadro we can very readily understand the combination of gases by volume. If we cause two liters of carbonic oxide to combine with one liter of oxygen, the product is not three liters of carbonic acid but two; for there are present the same number of molecules of $\mathrm{CO}_{2}$ as there were of CO and as. equal volumes of all gases contain the same number of molecules, an equal number of molecules occupy the

[^13]same volume, at the same temperature and pressure: hence we have
$$
2 \text { vols. } \mathrm{CO}+1 \text { vol. } \mathrm{O}_{2}=2 \text { vols. } \mathrm{CO}_{2} .
$$

This shows that the combination of the two gases is attended by a decrease in volume and that the resulting volume is two-thirds of that occupied by the mixture.

Similarly we have
2 vols. $\mathrm{H}_{2}+1$ vol. $\mathrm{O}_{2}=2$ vols. $\mathrm{H}_{2} \mathrm{O}$ (as steam)
I vol. $\mathrm{CH}_{4}+2$ vols. $\mathrm{O}_{2}=$ I vol. $\mathrm{CO}_{2}+2$ vols. $\mathrm{H}_{2} \mathrm{O}$ (as steam) or if the steam be allowed to condense I vol. $\mathrm{CH}_{4}+2$ vols. $\mathrm{O}_{2}=\mathrm{I}$ vol. $\mathrm{CO}_{2}+$ water.
This law together with the corrections for temperature, pressure and tension of vapor, already explained, furnish all the information necessary to calculate gas analyses.

For example let us calculate the percentages from the following analytical results on a sample of water gas.
Volume taken for analysis, . . . Ioo c.c.
Contraction due to absorption of $\mathrm{CO}_{2}$, . 0.0 c.c.

| " | " | " | "illuminants, | 12.6 c.c. |
| :--- | :--- | :--- | :--- | :--- |
| " | " | " | " oxygen, | 0.9 c.c. |
|  | " | " | CO, | 27.3 c.c. |

We have left 59.2 c.c. of the original ioo c.c. containing hydrogen, methane \&c., and nitrogen, 16.2 c.c. of this are withdrawn to the explosion tube and mixed with 32.3 c.c. of oxygen and then diluted with 3 I .4 c c. of air giving a total volume of 80.1 c.c.: this is then exploded and after allowing to cool the volume is found to be 53.4 c.c.

We have in the tube before explosion.
x Vols. $\mathrm{CH}_{4}+\mathrm{y}$ vols. $\mathrm{H}_{2}+\mathrm{m}$ vols. $\mathrm{N}_{2}+\mathrm{n}$ vols. $\mathrm{O}_{2}$.

After explosion this becomes
x vols. $\mathrm{CO}_{2}+(2 \mathrm{x}+\mathrm{y})$ vols. $\mathrm{H}_{2} \mathrm{O}$ (condensed) +m vols. $\mathrm{N}_{2}$ (unaffected) $+\mathrm{n}-(2 \mathrm{x}+\mathrm{y} / 2 \mathrm{y})$ vols. $\mathrm{O}_{2}$.

The volume of oxygen is diminished by a volume equal to twice that of the $\mathrm{CH}_{4}$ plus one-half that of the hydrogen.

The $\mathrm{CO}_{2}$ produced by the explosion is removed by dilute potassium hydroxide solution and the volume of the gas again measured $=45.8$ c.c. The contraction in volume produced by the removal of $\mathrm{CO}_{2}$ equals the volume of $\mathrm{CH}_{4}$ present, 7.6 c.c. The contraction in volume due to the explosion, 26.7 c.c., therefore represents the volume occupied by the hydrogen (condensed to water) and the decrease of oxygen equal to twice the volume of $\mathrm{CH}_{4}$ plus one half the volume of hydrogen. The $\mathrm{CO}_{2}$ produced takes the place of the $\mathrm{CH}_{4}$ originally present.

If we let $\mathrm{y}=$ vol. of hydrogen, we have:

$$
26.7=y+2(7.6)+1 / 2 y . \quad y=7.66 \text { c.c. }
$$

Or, the volume of hydrogen $=2 / 3$ (of contraction minus twice the volume of $\mathrm{CO}_{2}$ formed) (second absorption by $\mathrm{KOH})$.

As only a portion of the residual gas was taken for the explosion, the volumes obtained are referred to the original ioo c.c. by proportions:

$$
\begin{array}{lll}
\text { for } \mathrm{CH}_{4}, & \text { I } 6.2: 59.2:: 7.6: x . & x=27.77 \\
\text { c.c. } \\
\text { for } H_{2}, & \text { I6.2: } 59.2:: 7.66: y . & y=27.99 \text { c.c. }
\end{array}
$$

The results expressed in percentage by volume are: carbonic acid, none : illuminants, $\mathrm{I} 2.6 \%$ : oxygen, $0.9 \%$ : carbonic oxide, $27.3 \%$ : hydrogen, $28 \%$ : methane \&c., $27.7 \%$ : nitrogen (by difference) $3 \cdot 5 \%$.

For accurate work all volumes should be corrected
for temperature, pressure, and vapor tension as already explained.

The following are results on coal gas with the Elliott apparatus:

Volume taken for analysis ioo c.c.
Reading after treatment with KOH . ( $\mathrm{CO}_{2}$ ) o.o c.c.
" " " bromine (illuminants)
6.5 c.c.

Reading after treatment with alkaline pyrogallate $\left(\mathrm{O}_{2}\right) 7 \cdot 4$ c.c.

Reading after treatment with $\mathrm{Cu}_{2} \mathrm{Cl}_{2}$ and HCl (CO) i4.2 c.c.

Drawn off for combustion 15.8 c.c.
Volume after adding oxygen 48.0 c.c.

| " " |  |
| :--- | :--- | :--- |
| " | air 79.7 c.c |
| " | explosion $53.5 \mathrm{c.c}$ |

" washing with $\mathrm{KOH}_{46.0}$ c.c.
The volume of $\mathrm{CH}_{4}=\mathrm{CO}_{2}$ formed $=53.5-46=$ 7.5 c.c.

As the volume of hydrogen $=2 / 3$ of contractiontwice the $\mathrm{CO}_{2}$ formed: we have,

Volume of hydrogen $=2 / 3(26.2-15)=7.46$ c.c.
To refer these quantities to the original ioo c.c. we have, residual volume $=100-14.2$ c.c. $=85.8$ c.c. and for $H_{2}$, I $5.8: 85.8:: 7.46:: x . \quad x=40.5$ for $\mathrm{CH}_{4}$, I $5.8: 85.8:$ : $7.5:: y . \quad y=40.7$
So our results become: carbonic acid, none: illuminants, $6.5 \%$ : oxygen, $(7.4-6.5) 0.9 \%$ : carbonic oxide, (14.2-7.4) 6.8\%: hydrogen, $40.5 \%$ : methane \&c., $40.7 \%$ : nitrogen (by difference), $4.6 \%$.

## EXAMPLES.

1. Reduce twelve liters of oxygen, measured at $47^{\circ} \mathrm{C}$ and under a pressure of $782 \mathrm{~m} . \mathrm{m}$. of mercury, to the standard conditions. Ans. 10.5338 liters.
2. What will be the volume of nine liters of hydrogen (at the standard conditions) when heated to $120^{\circ} \mathrm{C}$ and under a pressure of $423 \mathrm{~m} . \mathrm{m}$. ?

Ans. 23.278 liters.
3. Given 27 c.c. of nitrogen at $14^{\circ} \mathrm{C}$ and 752 . I m.m. What will be its volume at $20^{\circ} \mathrm{C}$ and $767.8 \mathrm{~m} . \mathrm{m}$. ?

Ans. 27 c.c.
4. What is the weight of 77.2 c.c. of air measured over water at $27^{\circ} \mathrm{C}$ and $758 \mathrm{~m} . \mathrm{m}$. pressure? See tables. ${ }^{2 n s} 0.08742$ gram.
5. What is the weight of 17 liters of hydrogen, measured at $12{ }^{\circ} \mathrm{C}$ and 3 atmospheres pressure? Take 1 atmosphere $=760 \mathrm{~m} . \mathrm{m}$ of mercury.

Ans. 4.38354 grams.
6. What is the weight of 85 c.c. of $\mathrm{NH}_{3}$ gas measured over mercury at $140^{\circ} \mathrm{C}$ and under a pressure of 770 $\mathrm{m} . \mathrm{m}$. ? Given the tension of mercury vapor at $140^{\circ} \mathrm{C}=$ $1.76 \mathrm{~m} . \mathrm{m}$.

Ans. 0.04327 gram.
7. Find the density referred to air of chloroform vapor. Given the following data for Dumas' method.

Weight of bulb and air at $20.5^{\circ} \mathrm{C}$ and $763.9 \mathrm{~m} . \mathrm{m}$. $34.845^{1}$ grams.

Weight of bulb and vapor at $116.5^{\circ} \mathrm{C}$ and 763.9 m.m. 35.8430 grams.

Volume of air in bulb at $20.5^{\circ} \mathrm{C} 394.93$ c.c.
Ans. 4.Io
8. What is the density referred to hydrogen of a substance which gave the following results by Victor Meyer's method ?

Weight of substance taken 0.1307 gram.
Volume of air expelled (measuredover water) 25.8 c.c.
Temperature of air expelled $20^{\circ} \mathrm{C}$.
Height of barometer $763.9 \mathrm{~m} . \mathrm{m}$. Ans. 61.67.
9. What is the molecular weight of a substance which gave the following results by Hofmann's method.

Weight of substance used 0.1002 gram.
Volume of vapor 62.35 c.c.
Height of barometer at $21.5^{\circ} \mathrm{C} 771.5 \mathrm{~m} . \mathrm{m}$.
Height of column of mercury-(inside heating jacket) at $100^{\circ} \mathrm{C} 314 \mathrm{~m} . \mathrm{m}$.

Height of column of mercury-(outside heating jacket) at $26.5^{\circ} \mathrm{C}$ I 35 m .m.

Tension of mercury vapor at $100^{\circ} \mathrm{C} 0.27$ m.m.

$$
\text { Ans. } 114.27
$$

10. What is the density referred to air of a gas, which escapes in 14.5 minutes thror:gh an opening, through which, at the same temperature and pressure, the same volume of air requires 19.5 minutes?

$$
\text { Ans. } 0.55
$$

II. What is the density referred to hydrogen of a gaś, which escapes in 7 minutes 30 seconds from an opening, while the same volume of air under the same conditions requires 5 minutes 10 seconds?

Ans. 30.38.
12. An object whose specific gravity is $3.38\left(\mathrm{H}_{2} \mathrm{O}=\right.$ I.), weighed 39.7250 grams in air, when weighed with brass weights. What is its true weight?

Ans. 39.7335 grams.
13. An object whose specific gravity is 0.95 weighed 17.8540 grams in air, when weighed with brass weights. What is its true weight? Ans. 17.8740 grams.
14. A bar of gold Sp. Gr. 19.3 weighed 10.73685 kilos, when weighed in air with brass weights. What is the true weight? Ans. 10.73600 Kilos.
15. A piece of pyrrhotite, Sp. Gr. 4.5, weighed in air 47.3854 grams, when weighed with platinum weights. What is its true weight? Ans. 47.3954 grams.
16. A piece of antimony, Sp. Gr. 6.8, weighed 75 grams in air; the weights used were 50 grams brass, 20 and 5 grams platinum. What is the true weight?

$$
\text { Ans. } \quad 75.0048 .
$$

17. If 50 c.c. of $\mathrm{CH}_{4}, 50$ c.c. of $\mathrm{H}_{2}$ and 50 c.c. of $\mathrm{C}_{2} \mathrm{H}_{4}$ were mixed with 450 c.c. of oxygen and exploded. What would be the resulting volume at the same temperature and pressure? (Assume that the temperature is below $100^{\circ} \mathrm{C}$.).

Ans. 325 c.c.
18. Calculate the percentage by volume of a blast furnace gas, giving the following results:

Taken for analysis ioo c.c.
Volume, after washing with $\mathrm{KOH}\left(\mathrm{CO}_{2}\right) 99.4$ c.c.
" " " $\quad \mathrm{Br}$ (illuminants) 99.4 c.c.
" " " "Alkaline "pyro" $\left(\mathrm{O}_{2}\right) 99.4$ c.c.
Decrease in volume after explosion
(the whole used) 2.I c.c.
Removed by washing with KOH none.
Ans. $\quad \mathrm{CO}_{2} 0.6 \% . \quad \mathrm{CO} 34.3 \% . \quad \mathrm{H}_{2} \mathrm{I} .4 \% . \quad \mathrm{N}_{2} 63.7 \%$.
19. Calculate the percentage by volume of a producer gas giving the following results :
Volume taken for analysis ioo c.c.
" after washing with $\mathrm{KOH}\left(\mathrm{CO}_{2}\right) 98.5$ c.c.
" " $\quad$ " $\quad$ " Br (illuminants) 98.5 c.c.

Decrease in volume after explosion, the whole used, 15 c.c. Removed by washing with KOH 3 c.c.

Ans. $\mathrm{CO}_{2}, \mathrm{I} .5 \%$. $\mathrm{CO}, 23.5 \% . \mathrm{CH}_{4}, 3 \% . \mathrm{H}_{2}, 6 \%$. $\mathrm{N}_{2}$ by difference, $66 \%$.
20. Calculate the composition of a coal gas given the following data:
Volume taken for analysis iooc.c.
" after washing with $\mathrm{KOH}\left(\mathrm{CO}_{2}\right) 99.5$ c.c.
" " $\quad$ " $\quad$ " Br (illuminants) 95.5 c.c.

Decrease after explosion, one quarter used, 36.9 c.c.
Removed by washing with KOH Io.I c.c.
Ans. $\mathrm{CO}_{2}, 0.5 \%$. Illuminants ( $\mathrm{C}_{2} \mathrm{H}_{4} \& \mathrm{c}$.) $4 \% . \mathrm{O}_{2}$, $0.5 \% . \mathrm{CO}, 6 \% . \mathrm{CH}_{4} \& \mathrm{c}$., $40.4 \% . \mathrm{H}_{2}, 44.5 \% . \mathrm{N}_{2}$, by difference, $4.1 \%$.

2I. Calculate the percentage composition of an illumi nating gas from the following data. Volume taken for analysis 100 c.c.

Volume absorbed by KOH . . 3.2 c.c.

| " | " | Bromine | IO. 7 c.c. |
| :--- | :--- | :--- | :--- |
| ". | " | " alkaline pyrogallol | 2.7 c.c. |

To 16 c.c. of the residual gas 64 c.c. of air were added and the mixture exploded. The contraction was 21.4 c.c. Washing with KOH solution removed 4.9 c.c.

Ans. $\mathrm{CO}_{2} 3.2 \%$. Illuminants $10.7 \%$. $\mathrm{O}_{2} 2.7 \%$. $\mathrm{CO} 27.4 \%$. $\mathrm{CH}_{4}$ 17.15\%. $\mathrm{H}_{2} 27.05 \%$. $\mathrm{N}_{2}$ II. $8 \%$.
22. Calculate the composition of an illuminating gas given the following data. Volume taken for analysis 100 c.c. Volume after absorbing with absolute alcohol (hydrocarbons) 95.8 c.c. Volume after absorbing with KOH $\left(\mathrm{CO}_{2}\right) 93.2$ c.c. Volume after absorbing with fuming sulphuric acid, and then with KOH (illuminants) 85.8 c.c. Volume after absorbing with alkaline pyrogallol $\left(\mathrm{O}_{2}\right)$ 82 c.c. Volume after absorbing with cuprous chloride (CO) 6 г. 6 c.c.
i 6 c.c. of the residual gas was diluted to 80 c.c. with air and exploded.

Contraction after explosion 18.4 c.c. Further contraction on washing with KOH 3.5 c.c.

Ans. Hydrocarbons $4.2 \%$. $\mathrm{CO}_{2} 2.6 \%$. Illuminants $7.4 \%$. $\mathrm{O}_{2} 3.8 \%$. $\mathrm{CO} 20.4 \%$. $\mathrm{CH}_{4} \quad \mathrm{I} 3.5 \%$. $\mathrm{H}_{2} 29.3 \%$. $\mathrm{N}_{2}$ I $8.8 \%$.
23. Find the molecular weight of bromine. Given the following data for Dumas' Method. Weight of bulb and air at $760.7 \mathrm{~m} . \mathrm{m}$. and $24.5^{\circ} \mathrm{C} .51 .8384$ grams.

Weight of bulb and bromine vapor at $760.7 \mathrm{~m} . \mathrm{m}$. and $102^{\circ}$ C. 53. 1338 grams.

Weight of bulb and water at $24.5^{\circ}$ C. 37 I .3 grams.
To calculate the volume of the bulb $y$.
Let $x=$ weight of bulb, then, $51.8384-(y \times w t .1$ c.c. air) $=\mathrm{x}$.

Also 37 I. $3-(y \times$ wt. I c.c. water $)=x$.
So $51.8384-(\mathrm{y} \times .0012)=371.3-(\mathrm{y} \times 0.9972) . \quad y$ $=320.7$ c.c.

Taking the gram molecular volume as 22.4 liters the molecular weight of bromine is

Ans. 160.67.
24. Given the weight of a bulb filled with air at $24^{\circ}$ C. and $761 \mathrm{~m} . \mathrm{m}$. pressure 50.178 grams, the weight of the same bulb filled with water at $24^{\circ} \mathrm{C} .355 .6$ grams. What is the weight and the volume of the bulb?

$$
\text { Ans. } 49.8131 \text { grams. } 306.6 \text { c.c. }
$$

25. What is the volume of the products of the complete combustion of 5 grams of benzene $\mathrm{C}_{6} \mathrm{H}_{6}$, when measured at $70^{\circ} \mathrm{C}$. and $760 \mathrm{~m} . \mathrm{m}$. pressure? Given the weight of a liter of hydrogen 0.08973 gram.

$$
\text { Ans. } 10.85 \text { liters. }
$$

26. What is the volume occupied by the products of the complete combustion of io grams of $95 \% \mathrm{CH}_{3} \mathrm{OH}$ (the remaining $5 \%$ being water) at $4^{\circ} \mathrm{C}$. and $768 \mathrm{~m} . \mathrm{m}$. pressure? One liter of hydrogen weighs 0.08973 gram.

Ans. 6.70 liters.
27. What is the volume occupied by the products of the complete combustion of 12 grams of absolute alcohol at $120^{\circ} \mathrm{C}$. and $742 \mathrm{~m} . \mathrm{m}$. pressure? Given the weight of one liter of hydrogen 0.08973 gram.

Ans. 43.165 liters.
28. What is the volume of the water produced by the complete combustion of 13 liters of acetylene measured under the standard conditions? Given the weight of one liter of hydrogen 0.08973 gram. Ans. 10.4 c.c.
29. Calculate the volume of the products of the complete combustion of 2 grams of glucose $\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}$ at $17^{\circ} \mathrm{C}$. and $758 \mathrm{~m} . \mathrm{m}$. pressure. Given only the weight of a liter of hydrogen 0.08973 gram. Ans. 1.59 liters.
30. Calculate the volume occupied at $105^{\circ} \mathrm{C}$. and $760 \mathrm{~m} . \mathrm{m}$. by the products of the complete combustion of 100 c.c. of a gas, measured at $0^{\circ}$ C., containing $50 \%$ hydrogen, $40 \% \mathrm{CO}, 5 \% \mathrm{CO}_{2}$ and $5 \% \mathrm{~N}_{2}$ (by volume).

Ans. 138.4 c.c.

## CHAPTER IX.

## CALCULATIONS OF CALORIFIC POWER.

Before taking up the calculations of the calorific power of the usual fuels, a few words on thermo-chemistry are necessary, to serve as an introduction to this and the following chapter. We have already discussed the qualitative and quantitative aspects of a chemical reaction; it remains to show here the thermo-chemical relations expressed.

All chemical reactions are accompanied by the liberation or absorption of a definite amount of energy, which may manifest itself in various ways, such as heat or electricity. Let us consider the equation :
$\mathrm{Zn}+\mathrm{Cl}_{2}=\mathrm{ZnCl}_{2}$, as written this signifies that 65.4 parts by weight of zinc combine with 70.9 parts of chlorine to give 136.3 parts of zinc chloride ; but besides this, heat is liberated equivalent to 97,200 calories, when the quantities used are the atomic or molecular weights in grams, so

$$
\mathrm{Zn}+\mathrm{Cl}_{2}=\mathrm{ZnCl}_{2}+97,200 \text { calories. }
$$

In other words 65.4 grams of zinc and 70.9 grams of chlorine contain when uncombined potential energy equivalent to 97,200 calories more than that of 136.3 grams of zinc chloride ; consequently to decompose zinc chloride, into zinc and chlorine, energy must be expended, equivalent to that given up when combination took place or 97,200 calories per gram-molecule. This energy can be
conveniently supplied in the form of an electric current; and the calculation of the voltage necessary to decompose certain molecules will be discussed in the next chapter.

The heats of formation of many molecules have been determined and are usually expressed in terms of heat developed by the formation of the molecular weight in grams of the substance ; so that the numbers are directly comparable with the molecules taking part in reactions. This is not always the case however and care must be taken to ascertain whether the table is based on grammolecules, gram-equivalents or grams of the compound formed.

The unit of heat is the calorie, the amount of heat necessary to raise one gram of water from $4^{\circ}$ to $5^{\circ} \mathrm{C}$. : as the specific heat of water does not vary greatly with the temperature, a calorie is taken practically as the amount of heat necessary to raise one gram of water one degree centigrade. Other units in use are: the greater calorie, the heat necessary to raise one kilogram of water $I^{\circ} \mathrm{C}$, equal to 1000 calories: and a value denoted by K , introduced by Ostwald, the amount of heat necessary to raise one gram of water from $0^{\circ}$ to $100^{\circ} \mathrm{C}$, this is practically equal to 100 calories.*

The following are important thermo-chemical reactions:

$$
\begin{array}{lll}
\mathrm{H}_{2}+\mathrm{O}=\mathrm{H}_{2} \mathrm{O}+68400 \text { calories } & (684 \mathrm{~K}) \\
\mathrm{C}+\mathrm{O}=\mathrm{CO}+29000 & " & (290 \mathrm{~K}) \\
\mathrm{CO}+\mathrm{O}=\mathrm{CO}_{2}+68000 & " & (680 \mathrm{~K}) \\
\mathrm{C}+\mathrm{O}_{2}=\mathrm{CO}_{2}+97000 & " & (970 \mathrm{~K}) \\
\mathrm{S}+\mathrm{O}_{2}=\mathrm{SO}_{2}+71000 & " & (710 \mathrm{~K})
\end{array}
$$

[^14]We see from these the amounts of heat given up by the formation of 18 grams of water, 28 grams of carbonic oxide etc. For the purpose of calculating the calorific power of fuel, it will be more convenient to have the amount of heat formed by the combustion of one gram of hydrogen, carbon and sulphur. If $2+$ grams of hydrogen and 16 grams of oxygen give $18+$ grams of water and 68,400 calories: one gram of hydrogen will give $\frac{68,400}{2}$ or 34,200 calories : similarly one gram of carbon $\frac{97000}{12}$ or 8083 calories and one gram of sulphur $\frac{71000}{3^{2}}$ $=2219$ calories.

These heats of formation, so essential to the calculation of calorific power, are given various figures by different observers and it is a difficult matter to decide which to use. We shall adopt the following as having the greatest probability of accuracy and at the same time being in most general practical use.
One gram carbon to carbonic acid 8080 calories
One gram hydrogen to water (condensed) 34500 calories One gram sulphur to sulphur dioxide 2220 calories
These numbers are the same in greater calories when one kilogram of the element is burned.

It will be seen from the preceding variations between the values of the fundamental data, that considerable uncertainty exists concerning thermo-chemical figures. The relative accuracy is much greater than the absolute; so the data employed should always be taken from the same source and if possible obtained by the same method.

With this introduction we proceed to the consider. ation of the calculations of the calorific power of fuel from a practical standpoint.

## CALORIFIC POWER OF FUEL.

The calorific power of any solid fuel such as coal can be determined by three methods.
ist. By combustion in a calorimeter.
2nd. By calculation, from the results of an ultimate analysis.

3rd. By calculation, from the weight of lead reduced from litharge by fusion with a weighed quantity of the coal.

Only the first and second methods are applicable to liquids or gases.
ist. Of these three methods the first is the most accurate, as it affords a direct measure of the heating power of the fuel when burned under the most favorable conditions. The calculations involved do not specially belong to analytical chemistry, so the reader is referred to Poole on the Calorific Power of Fuels, for both a description of the apparatus and directions for the calculations.
and. The second method is largely used and is important for analysts, as they usually have the apparatus required to get the analytical results, while they are not often supplied with an expensive calorimeter.

For commercial purposes, calorific power is expressed in four ways :
ist. In calories per kilogram (greater calories), for example 7000 calories means that one kilogram of the fuel will raise the temperature of 7000 kilograms of water one degree centigrade.

2nd. In British thermal units (B.T.U.) or the amount of heat necessary to raise one pound of water one degree Fahrenheit.

3 rd. In kilograms of water evaporated per kilogram of coal.

4th. In pounds of water evaporated per pound of coal.
The relations between these various ways of expressing calorific power are not complicated. To convert calories per kilogram into British thermal units it is only necessary to multiply by 1.8 for if a kilogram of coal heats 7000 kilograms of water one degree centigrade, one pound of coal will heat 7000 pounds of water one degree centigrade, and it only remains to multiply by the factor for converting centigrade to Fahrenheit degrees. Conversely to change B.T.U. to calories divide by 1.8 or multiply by $5 \%$.

To find the number of kilograms of water evaporated by a kilogram of fuel, divide the calorific power (in calories per kilogram) by 536 , the number of calories required to convert one kilogram of water at $100^{\circ} \mathrm{C}$ into steam at $100^{\circ} \mathrm{C}$. If it should be necessary to raise the water from some temperature, for example $15^{\circ} \mathrm{C}$ to $100^{\circ} \mathrm{C}$ and then evaporate it : divide by $536+(100-15)$ or 621 . As the specific heat of water is taken as unity.

To find the number of pounds of water evaporated by a pound of fuel, divide the calorific power expressed in B.T.U. by $965(536 \times 1.8)$. For example, how many pounds of water will be heated from $59^{\circ} \mathrm{F}$. to $212^{\circ} \mathrm{F}$. and evaporated by one pound of a coal whose calorific power is 7000 (calories per kilogram)? $7000 \times 1.8=$ 12,600 B.T.U. It requires $212-59=153$ B.T.U. to heat a pound of water from $59^{\circ} \mathrm{F}$. to $212^{\circ} \mathrm{F}$. and 965 B.T.U. to convert it into steam at $212^{\circ} \mathrm{F}$ : So, $12600 \div(153+965)=11.27$ pounds.

## CALORIFIC POWER OF SOLIDS.

Given the composition of perfectly dry oak wood: carbon, $50.16 \%$ : hydrogen, $6.02 \%$ : oxygen, $43.36 \%$ : nitrogen, $0.09 \%$ : ash, $0.37 \%$ : to calculate its calorific power.

One kilogram will contain :
Carbon 501.6 grams Hydrogen 60.2 "

Nitrogen 0.9 grams Oxygen 433.6

Ash 3.7
As part of the hydrogen is already in combination with oxygen, only the excess over the amount necessary to form water with all the oxygen is available as fuel: as 16 parts of oxygen combine with 2 of hydrogen, the hydrogen already in combination with oxygen will be $433.6 \div 8=54.2$ grams: So we have available as fuel 6 grams of hydrogen and 501.6 grams of carbon.
0.006 kilogram hydrogen $\times 34500=207$ calories
0.5016 " carbon $\times 8080=4053$

Theoretical heating power $=4260$ calories.
If the products of combustion escape at a temperature of or above $100^{\circ} \mathrm{C}$., the heat given up by the condensation of the steam, which is lost, must be subtracted. This is found as follows: 60.2 grams of hydrogen give $9 \times 60.2=54 \mathrm{I} .8$ grams of water; and as 536 calories are required to convert one kilogram of water at $100^{\circ}$ to steam at $100^{\circ}$, the heat lost in this case will be equal to that required to change 541.8 grams of water into steam at $100^{\circ} \mathrm{C}$ or $536 \times 0.5418=290$ calories : so the available heat becomes 3970 calories. When the fuel has also hygroscopic moisture this must also be evaporated and if the products are not condensed, the heat necessary to do this must be deducted.

To calculate the calorific power of a coal whose composition is: carbon, $80.55 \%$; hydrogen, $4.50 \%$; sulphur, $0.54 \%$; oxygen, (by difference) $2.70 \%$; nitrogen, $1.08 \%$; moisture, $2.92 \%$; ash, $7.71 \%$.

The nitrogen and ash are inert and simply diminish the available calorific power by the heat expended in bringing them to the temperature of the products of combustion, this amount is relatively very small and is neglected.

The moisture is objectionable as it must be raised to $100^{\circ} \mathrm{C}$ and then evaporated, thus rendering latent a portion of the heat evolved which can however be recovered if the products of combustion are cooled below $100^{\circ} \mathrm{C}$.

The available hydrogen is calculated as before,

$$
4.50-\frac{2.70}{8}=4.16 \%
$$

One kilogram of the coal contains available as fuel : 41.6 grams of hydrogen giving i435.2 calories

| 805.5 | " | carbon " | 6508.4 |
| :---: | :---: | :---: | :---: |
| 5.4 | " " sulphur " | " 2.0 | " |
| Theoretical calorific power | $=7943.6$ |  |  |

This on the basis of the condensation of the aqueous vapor produced which will then give up heat equal to that required to vaporize it, so no deduction is made. If the products are allowed to escape without condensation of the aqueous vapor, as is always the case in practice; the number of calories necessary to convert into vapor all the water present must be subtracted.

This will be, $9 \times 4.5$ (the percentage of hydrogen) $=$ 405 grams per kilogram plus moisture 29.2 grams $=$ 434.2 grams or 0.4342 kilogram; and $0.434^{2} \times 536$ (the number of calories necessary to convert one kilo-
gram of water at $100^{\circ} \mathrm{C}$ to steam at $100^{\circ} \mathrm{C}$ ) gives 232.7 calories. So under these conditions the available calorific power of the coal is 7710.9 calories. This can be corrected further for the heat necessary to raise the fuel to $100^{\circ} \mathrm{C}$ and for the heat lost by the escape of the products of combustion at temperatures above $100^{\circ} \mathrm{C} \& \mathrm{c}$.

Taking 77II as the calorific power of the coal, let us see the quantities of water it will evaporate.

Kilograms of water at $100^{\circ} \mathrm{C}$ per kilogram of coal

$$
\text { will be } \frac{7711}{536}=14.38
$$

Kilograms of water at $15^{\circ} \mathrm{C}$ per kilogram of coal

$$
\text { will be } \frac{7711}{536+(100-15)}=12.41 .
$$

Pounds of water at $212^{\circ} \mathrm{F}$. per pound of coal

$$
\text { will be } \frac{77 \mathrm{II} \times \mathrm{I} .8}{965} \text { or } \frac{77 \mathrm{II}}{536}=14.38
$$

Pounds of water at $40^{\circ} \mathrm{F}$. per pound of coal

$$
\text { will be } \frac{77 \mathrm{II} \times 1.8}{965+(2 \mathrm{I} 2-40)}=12.21
$$

This discussion can be summed up by the following formulae. Let x be the calorific power of the fuel, and let C,H,O,S and W be the weights of carbon, hydrogen, oxygen, sulphur and hygroscopic water, expressed in kilograms: then we have,

$$
x=8080 \mathrm{C}+34500\left(\mathrm{H}-\frac{\mathrm{O}}{8}\right)+2220 \mathrm{~S}
$$

An expression for the theoretical calorific power. And, $x=8080 C+34500\left(H-\frac{O}{8}\right)+2220 \cdot S-536(W+9 H)$

For the available calorific power when the products of combustion are not condensed. The heat generated
by the sulphur can usually be omitted without materially affecting the results.

Numerous formulae are given by different authorities, which differ somewhat from the preceding and attempt to bring the results by calculation nearer those obtained by the calorimeter, or the conditions of actual practice. Those given agree very closely with that of Dulong as recommended by the committee of the American Chemical Society.*

This method of calculation is based on Welter's rule, where the assumption is made that the oxygen present is all combined with hydrogen or that we shall offset the heat of formation of the molecules present by deducting the quantity of heat which would be produced if the oxygen present combined with hydrogen. This is a very weak point in the method of obtaining the calorific power from the percentage composition.

In the case of anthracite the error will be small because the combustible material is nearly all carbon. With a bituminous coal the error is liable to be much larger, while with wood the attempt to offset the unknown heat of combination of cellulose and the other complex organic compounds present by this deduction is very unsatisfactory.

Ostwald has recommended subtracting the oxygen present from the carbon instead of from the hydrogen as giving results closer to those obtained by actual combustion. $\dagger$

CALORIFIC POWER OF LIQUIDS.
The calculation can be made as already given but the results are necessarily unsatisfactory unless the heat of

[^15]combination is considered, which is not readily obtained for mixtures like crude petroleum, etc. For alcohol the calculation could be made, but for all commercial liquid fuels the determination of calorific power should be made by the calorimeter.

## CALORIFIC POWER OF GASES.

In connection with the calorific power of gases the discrepancy in results between the calculated and actual calorific power of solids and liquids is best explained. Let us consider the thermo-chemical reactions:

$$
\begin{aligned}
\mathrm{C}+\mathrm{O}_{2} & =\mathrm{CO}_{2}+970 \mathrm{~K} \\
2 \mathrm{H}_{2}+\mathrm{O}_{2} & =2 \mathrm{H}_{2} \mathrm{O}+2(684) \mathrm{K} \\
\mathrm{C}+2 \mathrm{H}_{2} & =\mathrm{CH}_{4}+218 \mathrm{~K} \text { hence } \\
\mathrm{CH}_{4}+2 \mathrm{O}_{2} & =\mathrm{CO}_{2}+2 \mathrm{H}_{2} \mathrm{O}+2 \mathrm{I} 20 \mathrm{~K} \\
2 \mathrm{I} 2 \mathrm{O}=970 & +2(684)-2 \mathrm{I} 8,
\end{aligned}
$$

or the heat produced by the combustion of 16 grams of $\mathrm{CH}_{4}$ is 2 I 20 K ; less by 2 I 8 K than the heat produced by the burning of 12 grams of carbon and four grams of hydrogen.

In solids and liquids when we do not know the chemical compounds and only the ultimate composition we may be led into similar errors.

Sixteen grams of methane $\left(\mathrm{CH}_{4}\right)$ gave 2120 K hence one gram gives 132.5 K or 13250 calories and one kilogram the same number of greater calories. In the table at the back of this book, we find the weight of a liter of methane to be 0.71502 gram. The weight of a cubic meter is 1000 times this or an equal number of kilograms. The calorific power of a cubic meter will therefore be $13250 \times 0.715=9474$ calories (greater), and as a cubic meter $=35.3 \mathrm{I} 7 \mathrm{I}$ cubic feet, the calorific power per cubic foot is 268.2 calories. To convert this to B.T.U. per
cubic foot it must be multipled by 3.97 giving 1065 as the calorific power of methane per cubic foot.

Now that we see the relation of these values we can conveniently use the following figures to calculate the theoretical calorific power of a gas per cubic foot measured at $0^{\circ} \mathrm{C}$ and $760 \mathrm{~m} . \mathrm{m}$. pressure

Hydrogen, $\quad \mathrm{H}_{2} \quad 347.2$ B.T.U per cubic foot.
Carbonic oxide CO. 341.4 " " " "
Methane $\mathrm{CH}_{4}$ 1065 " " " "
llluminants $\mathrm{C}_{2} \mathrm{H}_{4}+\mathrm{C}_{3} \mathrm{H}_{6} 2000$ B.T.U. per cubic foot. If we assume the initial temperature of the gas to be $60^{\circ} \mathrm{F}$. and the products to escape at $328^{\circ} \mathrm{F}$., without condensation, these figures become : *

| Hydrogen | $\mathrm{H}_{2}$ | 264. | B.T.U. per cubic foot |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Carbonic oxide | CO | 307. | " | ، |  |  |
| Methane | $\mathrm{CH}_{4}$ | 853. | " |  |  |  |
| Illuminants | $\mathrm{H}_{4}+\mathrm{C}$ | $\mathrm{H}_{6}$ I 700 |  |  |  |  |

Given a gas of the following composition, to calculate its theoretical calorific power in B.T.U. per cubic foot: hydrogen, $50.4 \%$ : methane, $33.7 \%$ : illuminants, $5.2 \%$ : carbonic acid, $2.6 \%$ : carbonic oxide, $5.8 \%$ : oxygen, $0.8 \%$ : nitrogen, $1.5 \%$.

As all gases expand equally the percentage composition by volume is not affected by the temperature at which the analysis was made. In this case the oxygen cannot be in combination with the hydrogen, so we have available as fuel :

Hydrogen $0.504 \mathrm{Cu} . \mathrm{ft} . \times 347.2=174.98$ B.T.U.
Methane 0.337 " $\times 1065=358.90$ "
Illuminants 0.052 " $\times 2000=104.00$ "

[^16]Carbonic oxide $0.058 \mathrm{Cu} . \mathrm{ft} . \times 34 \mathrm{I} .4=19.80$ B.T.U.
Theoretical calorific power per Cu. ft. 657.68 B.T.U. To convert this to calories per cubic meter multiply by 8.896: which gives 585 I.

The available calorific power, under the conditions stated, is found by using the values in the second table.

Many corrections might be added and other calculations, such as the volume of air required, the volume of the products of combustion, calorific intensity \&c. Some of these can be done by the methods given under the calculations of gases, the others seem out of the sphere of analytical chemistry.

CALORIFIC POWER FROM WEIGHT OF LEAD REDUCED.
The method of calculating calorific power from the weight of lead reduced from litharge by a gram of the fuel is only suitable for coal or coke and is only valuable when the average weight of three lead buttons is multiplied by a factor proper for the fuel.

This factor should be obtained by comparison with the calorimeter and will be the calories developed by one gram divided by the lead reduced from litharge by one gram. When this is once obtained it will give satisfactory results with similar coals.

Berthier's idea that the calorific power was directly proportional to the oxygen consumed, i.e. the lead reduced, is disproved by the following :

$$
\mathrm{C}+2 \mathrm{PbO}=2 \mathrm{~Pb}+\mathrm{CO}_{2}
$$

12 parts of carbon reduce 414 parts of lead hence,
r kilogram of carbon reduces 34.5 kilograms of lead.
I kilogram of carbon gives 8080 calories, hence,
the lead reduced times $\frac{8080}{345}$ or 234.2 gives the calorific
power. The factor for hydrogen is obtained similarly:

$$
\mathrm{H}_{2}+\mathrm{PbO}=\mathrm{Pb}+\mathrm{H}_{2} \mathrm{O} .
$$

I kilogram of hydrogen would reduce 103.5 kilograms of lead, and as one kilogram gives 34500 calories, the

$$
\text { factor is } \frac{34500}{103.5} \text { or } 333.33 \text {. }
$$

So it is evident that the more volatile matter, hydrocarbons \&c., the coal contains, the higher must be the factor used.

When no better means of determining calorific power is available the weight of lead reduced by one gram times 240 for an anthracite or times 268.3* for a bituminous coal, will give approximately the calorific power.

For a discussion of the calculations required in using the bomb calorimeter the student is referred to an article by Professor Atwater and Dr. Snell on a "Description of a Bomb Calorimeter and Method of its Use" published in the Journal of the American Chemical Society, July, 1903, Vol. XXV, p. 659-699.

[^17]
## EXAMPLES.

I. Find the theoretical calorific power of wood, whose composition is : carbon, $40 \%$; hydrogen, $4.8 \%$; oxygen, $33.8 \%$; nitrogen, $0.4 \%$; ash, $1 \%$; hygroscopic water, $20 \%$. Assuming the wood to be at $100^{\circ} \mathrm{C}$ and that the aqueous vapor is condensed.

Ans. 3430.4 calories.
2. Find the calorific power of peat, whose composition is : carbon, $39.3 \%$; hydrogen, $3.9 \%$; oxygen, 23.2 $\%$; ash, $7.3 \%$; water, $26.3 \%$. Assuming that the products of combustion escape at $100^{\circ} \mathrm{C}$. without condensation. Ans. 3191.3 calories.
3. Find the theoretical calorific power of a coal, whose composition is : carbon, $83.75 \%$; hydrogen, 4 . I 3 $\%$; oxygen. $2.65 \%$; nitrogen, $0.85 \%$; sulphur, $0.57 \%$; water, $0.80 \%$; ash, $7.25 \%$. Ans. 8090.6 calories.
4. In the preceding example, how many calories must be deducted if the aqueous vapor is not condensed?

Ans. 203.5 .
5. Find the theoretical calorific power in B.T.U. of a coal whose composition is: carbon, $70.50 \%$; hydrogen, $4.76 \%$; oxygen, $15.71 \%$; nitrogen, $1.36 \%$; sulphur, $1.39 \%$; ash, $6.28 \%$ Ans. 12048.
6. How many kilograms of water at $20^{\circ} \mathrm{C}$ will be evaporated by one kilogram of a coal, whose calorific power is 13535 B.T.U.? Ans. 12.2
7. How many pounds of water at $25^{\circ} \mathrm{C}$ will be evaporated by a coal whose calorific power is 8000 ?
Ans. I3.I
8. How many kilograms of water at $60^{\circ} \mathrm{C}$ will be evaporated by a coal whose calorific power is II270 B.T.U ?

Ans. 10.86
9. What is the difference between the calculated available calorific powers of ethyl and methyl alcohol.

Ans. 2000 calories (in round numbers).
10. What is the calorific power of a natural gas, whose composition is: methane, $96.50 \%$; illuminants, $1 \%$; carbonic oxide, $0.5 \%$; oxygen, $2 \%$; in B.T.U. per cubic foot? Gas and products at $0^{\circ} \mathrm{C}$.

$$
\text { Ans. } 1049 .
$$

Ir. What is the calorific power of a coal gas, whose composition is: hydrogen, $50.4 \%$; methane, $33.7 \%$; illuminants, $5.2 \%$; carbonic acid, $2.6 \%$; carbonic oxide, $5.8 \%$; oxygen, $0.8 \%$; nitrogen, $1.5 \%$; in B.T.U. per cubic foot? Assume that the gas enters at $60^{\circ} \mathrm{F}$ and the products of combustion escape at $328^{\circ} \mathrm{F}$.

$$
\text { Ans. } 527 .
$$

12. What is the calorific power of the following water gas: Hydrogen, $55 \%$; methane, $5.75 \%$; illuminants, $\mathrm{I} .20 \%$; carbonic acid, $4.05 \%$; carbonic oxide, $31.00 \%$; nitrogen, $3 \%$; in calories per cubic meter? Gas and products at $0^{\circ} \mathrm{C}$. Ans 3398.

## CHAPTER X.

## ELECTRIC AND ELECTROLYTIC CALCULATIONS FOR DIRECT CURRENTS.

The calculations described in this chapter, although not essential to analytical chemistry, are added because electricity is so largely employed for both laboratory and industrial operations, and it is advisable that a chemist be able to make the ordinary calculations involved in its use. In order to make the description as concise as possible the subjert is treated differently from the preceding chapters, and the important laws are expressed by formulæ, many of which are taken from an article by Prof. Crocker on the Theory of Electro-metallurgy.*

## ELECTRIC CALCULATIONS.

The ampere is the unit of current, that is the rate of flow; it is the strength of current which when passed through a solution of silver nitrate in water, under certain standard conditions, will deposit silver at the rate of 0.00 III 8 gram per second. Five amperes will deposit five times this amount every second. So to deposit 1.3416 grams of silver from an aqueous solution of silver nitrate in ten minutes requires two amperes; for

$$
\frac{1.3416}{0.001118 \times 600}=2
$$

The coulomb or ampere-second is the unit of quantity. It is the quantity of electricity which flows along a

[^18]conductor in one second when the current is one ampere. The total quantity or number of coulombs flowing in a given time is equal to the strength of current in amperes multiplied by the time in seconds or expressed in symbols
\[

$$
\begin{aligned}
& \quad \mathrm{Q}=\mathrm{Ct} \\
& \text { when } \begin{array}{l}
\mathrm{Q}=\text { quantity in coulombs } \\
\mathrm{C}=\text { strength of current in amperes } \\
\mathrm{t}
\end{array}=\text { time in seconds }
\end{aligned}
$$
\]

In dealing with large quantities of electricity the ampere-hour is used as a unit, an ampere flowing for an hour. This is 3600 coulombs.

If, for example, I. 5 amperes flow for 45 minutes the number of coulombs that have passed will be
I. $5 \times 45 \times 60=4050$ equal to I.I 25 ampere-hours.

The ohm is the unit of resistance. It is the resistance offered to an unvarying electric current by a column of mercury at $0^{\circ} \mathrm{C}$, one square millimeter in cross section and 106.3 centimeters long.

The resistance of a conductor, whether solid or liquid, to the passage of electricity has been found to depend upon its dimensions and the material of which it consists. For a given material it varies directly as the length and inversely as the area of the cross section.

The specific resistance of any material is the resistance measured between opposite faces of a cube of the material one square centimeter in area.

The resistance of any conductor is given by the formula,

$$
\begin{equation*}
\mathrm{R}=\rho \frac{\mathrm{l}}{\mathrm{a}} \tag{2}
\end{equation*}
$$

in which
R is the resistance of the conductor in ohms
$\rho$ is the specific resistance of the material in ohms
1 is the length in centimeters, and
-a is the area of the cross-section in square centimeters.

Therefore, if the specific resistance of a conductor is known the total resistance can be calculated from its dimensions. To find the resistance of 200 meters of Ger-man-silver wire having a cross section of 10 square millimeters; given the specific resistance of Germansilver as 0.0000209.* Reduce the area to square centimeters and the length to centimeters and the resistance

$$
\text { is } 0.0000209 \times \frac{20000}{0.1}=4.18 \mathrm{ohms}
$$

Similarly, if a glass tube, 20 centimeters long with an internal cross section of 2 square centimeters, is filled with a solution of zinc sulphate whose specific resistance is 30 ohms, the total resistance will be

$$
30 \times \frac{20}{2}=300 \mathrm{ohms}
$$

The specific resistance is not absolutely constant but changes with the temperature. In the case of all metals it increases with the temperature while for carbon, selenium, liquids and solutions it diminishes as the temperature rises. For aqueous solutions it naturally varies with their strength.

Conductors are connected in series when the current passes through one after the other; in parallel, when they are connected side by side so as to furnish more than one path for the current. The total resistance of a number of separate resistances connected in series is

[^19]equal to their sum. If two paths of equal resistance are offered, the total resistance is only one half, as this is equivalent to doubling the cross section of the conductor, or the resistance of a number of equal resistances in parallel is equal to the resistance of one divided by the number so connected.

Conductance is the reciprocal of resistance, or the ease with which a current is allowed to pass. The total conductance of a number of separate conductances connected in parallel is equal to their sum. Thus five conductors each of 50 ohms resistance, connected in series give a resistance equal to their sum, 250 ohms; while connected in parallel they give the resistance of one divided by the number, io ohms. If three resistances of 20,50 and 80 ohms respectively, are connected in series their total resistance is 150 ohms; while if connected in parallel their resistance is I2.I2 ohms; for their respective conductances will be $\frac{1}{20}, \frac{I}{50}$ and $\frac{I}{80}$ and their total conductance the sum of the three, 0.0825 . So that their total resistance is the reciprocal of 0.0825 or 12.12 ohms.

The volt is the unit of electromotive force or electrical pressure.

The relations between electromotive force, current, and resistance are expressed by Ohms Law; that the electromotive force acting between the extremities of any part of a circuit is the product of the strength of the current and the resistance of that part of the circuit, or

$$
\begin{align*}
\mathrm{E} & =\mathrm{C} \mathrm{R} \\
\text { or transposed } \mathrm{C} & =\frac{\mathrm{E}}{\mathrm{R}} \tag{3}
\end{align*}
$$

To comply with Ohms Law and the definitions of the ampere and ohm the unit of electromotive force, the volt
must be that electromotive force which steadily applied to a conductor whose resistance is one ohm will produce a current of one ampere.

The Clark cell at $15^{\circ} \mathrm{C}$ is the most constant source of electromotive force and is used as a standard. It gives an electromotive force of 1.434 volts.

Ohms law, equation (3) states that the amperes flowing in any circuit are equal to the volts divided by the ohms. This is the most important electrical law for by it when any two of the quantities involved are known the third may be determined. For instance if a conductor of io ohms resistance has flowing through it 3 amperes, the voltage measured between its ends must be $10 \times 3=30$ volts. Again if 18 volts are applied to the ends of a conductor of 9 ohms resistance the current will be $18 \div 9=2$ amperes. Finally if 0 . 1 of an ampere is desired from a source whose electromotive force is two volts, the total resistance of the circuit must be 20 ohms for as $E=C R . \quad R=\frac{E}{C}$ and $2 \div 0.1=20$ ohms.

We are now in a position to consider the relations between electrical energy, heat and power.

Joule has shown by experiment that the relation between the heat developed in a circuit and the current flowing through it is expressed by the equation

$$
\begin{equation*}
\mathrm{V}=\mathrm{C}^{2} \mathrm{Rt} \times 0.24 \tag{4}
\end{equation*}
$$

When
C is the current in amperes
R is the resistance in ohms
t is the time in seconds that the current has passed V is the heat in calories.

Consequently 2 amperes passing through 5 ohms for io seconds develop

$$
4 \times 5 \times \text { 10 } \times 0.24=48 \text { calories. }
$$

The constant 0.24 can be eliminated from equation (4) if instead of expressing the heat developed in calories we measure it in joules: for the joule, the electrical unit of heat, is 0.24 of a calorie.*

So if we designate the heat produced in joules by W the expression becomes

$$
\begin{equation*}
W=C^{2} R t \tag{5}
\end{equation*}
$$

and the heat developed by 2 amperes passing through 5 ohms for 10 seconds is $4 \times 5 \times 10=200$ joules.

Equation (5) may be written $\mathrm{W}=\mathrm{C} \mathrm{t} \times \mathrm{C}$ R. But we have already seen from equation (I) that $Q=C t$ and from Ohms law that $E=C R$; substituting these values we get:

$$
\begin{equation*}
W=Q E \tag{6}
\end{equation*}
$$

This equation (6) shows that the heat, measured in joules, generated in a conductor is equal to the number of coulombs that have passed multiplied by the voltage between the ends of that conductor.

For example, if 1000 coulombs (io amperes for one minute and forty seconds) have passed through a conductor, the voltage between whose ends is io; there have been generated in that time 1000 joules, equal to 238 . $1 \dagger$ calories.

Since heat is a form of energy, the energy applied to the conductor expressed in joulesis Q E. So that the

[^20]rate of work or power expressed in joules per second is $\frac{Q E}{t}$ or since $\frac{Q}{t}=C$ from equation (I); the power ex. pressed in joules per second equals C E.

A joule per second is called a watt so if we designate the power expressed in watts by P we have

$$
\begin{equation*}
P=C E \tag{7}
\end{equation*}
$$

or the number of watts in any electrical circuit is equal to the product of the amperes and the volts. A circuit in which 4.2 amperes are flowing at a pressure of 100 volts is performing work at the rate of 420 watts, corresponding to 100 calories, per second.

The relations between the electrical and mechanical units of power are as follows :-

Rowland has shown that it requires 780 foot pounds of energy to heat one pound of water one degree Fahrenheit, or 3.1 foot-pounds to heat one gram of water one degree centigrade, one calorie. Since one calorie is equal to 4.2 joules, one foot-pound is equal to 1.356 joules or one joule equal to 0.737 foot-pound.

550 foot-pounds therefore equal 746 joules, and since 550 foot-pounds per second are one horse-power and a joule per second is a watt, 746 watts equal one horsepower.

The practical unit for measuring large quantities of electrical power is the kilowatt, one thousand watts. This is equal therefore to 737 foot-pounds per second or approximately $11 / 3$ horse-power.

## ELECTROLYTIC CALCULATIONS.

When an electric current passes between platinum plates immersed in water acidified with sulphuric acid,
water is decomposed, oxygen is liberated at the platinum anode and hydrogen at the platinum cathode: anode and cathode are the names given to the electrodes by which the current enters (anode) and leaves (cathode) the liquid. - There is no liberation of hydrogen or oxygen except at the contact of the liquid with the electrodes. This chemical decomposition effected by the electric current is called electrolysis and the bath or material which undergoes decomposition the electrolyte.

Electrolytes may be solids, liquids, or as recent experiments have shown, gases. Silver iodide is an example of a solid electrolyte, while as liquid electrolytes we have solutions of mineral salts and acids as well as many fused salts. An electrolyte must recessarily be a conductor of electricity and in the case of liquids be ionized. Liquids such as pure water, ether, and carbon bisulphide which are not perceptibly ionized are not considered electrolytes.

The constituents into which the electrolyte is split up by the current are called ions; that which is liberated at the anode is the anion, that which is liberated at the: cathode the cathion. With very few exceptions an element or radical is always liberated at the same electrode. Ostwald* gives the following classification of ions-

## CATHIONS.

Monovalent: H (in acids) K. Na. Li. Cs. Rb. Tl. Ag. $\mathrm{NH}_{4} . \mathrm{NH}_{3} \mathrm{R}$ to $\mathrm{NR}_{4}$ ( R being an organic radical) Cu (cuprous), Hg (mercurous).

Divalent: Ca. Sr. Ba. Mg. Fe (ferrous), Cu (cupric), $\mathrm{Pb} . \mathrm{Hg}$ (mercuric), Co. Ni. $\mathrm{Zn} . \mathrm{Cd}$.

[^21]Trivalent: Al. Bi. Sb. Fe (ferric) and some of the rarer earth metals.

Tetravalent Sn (?). Zr.

## ANIONS.

Monovalent : OH (in bases) F. Cl. Br. I. $\mathrm{NO}_{3} \cdot \mathrm{ClO}_{3}$. $\mathrm{ClO}_{4} . \mathrm{BrO}_{4} . \mathrm{MnO}_{4}$ (in permanganates) and the anions of all other monobasic acids the (acid molecule minus one hydrogen which goes to the cathode).

Divalent: S. Se. Te (?). $\mathrm{SO}_{4} . \mathrm{SeO}_{4} . \mathrm{MnO}_{4}$ (in manganates), and the anions of dibasic acids.

Tri-to hexavalent: The anions of the tri-to hexavalent acids. Elementary anions with a valency of more than two are not known.

The quantity of the ions deposited by the passage of a current through an electrolyte was shown by Faraday to be very simply related to the quantity of electricity which passes.

Faraday's first law of electrolysis states: that the quantity of an electrolyte decomposed by the passage of a current of electricity is directly proportional to the quantity of electricity which passes through it. So as long as the quantity of electricity remains the same it is immaterial, so far as quantity deposited is concerned, whether the electricity passes as a very intense current for a short time or as a very weak current for a long time.

Faraday's second law of electrolysis states : that, if the same quantity of electricity passes through different electrolytes, the weights of the different ions liberated will be proportional to the chemical equivalents of the ions. Thus if the same current passes through a series of electrolytes from which it liberates as ions oxygen,
hydrogen, silver, and chlorine, then for every 8 grams of oxygen evolved there will be liberated 1.008 grams of hydrogen 107.93 grams of silver and 35.45 grams of chlorine.

The electrochemical equivalent of a substance is the weight in grams deposited by the passage of one coulomb of electricity. Using this, Faraday's laws can be comprised in the statement: that the number of grams of an ion deposited during the passage of a current through an electrolyte is equal to the number of coulombs that have passed multiplied by the electrochemical equivalent of the ion. Since one ampere per second, from the definition of unit of current, deposits 0.00 II 8 gram of silver and the chemical equivalent of silver is 107.93, the weight of any other element liberated by one ampere per second will be found by the proportion.

$$
\text { 0.00III8 : x : : } 107.93: \text { A. }
$$

in which A is the chemical equivalent of the element, or

$$
x=\frac{A(0.001 \text { I } 18)}{107.93}
$$

Therefore since $\frac{0.001118}{107.93}=0.00001036$, the total weight deposited must be:

$$
\begin{equation*}
\mathrm{w}=0.00001036 \mathrm{ACt} \tag{8}
\end{equation*}
$$

In which-
$\mathbf{w}$ is the weight in grams deposited.
$A$ is the chemical equivalent, that is the atomic weight divided by the valency of the deposited ion.

C is the current in amperes and
$t$ is the time in seconds that the current flows.

Expressing the time in hours and denoting it by N , equation (8) becomes:

$$
\begin{equation*}
\mathrm{w}=0.0373 \mathrm{~A} \mathrm{C} \mathrm{~N} . \tag{9}
\end{equation*}
$$

C N being ampere-hours.
By transposing this equation, we get an expression for the amount of current required to deposit a given weight in a given time.

$$
\begin{equation*}
\mathrm{C}=\frac{26.8 \mathrm{w}}{\mathrm{AN}} \tag{io}
\end{equation*}
$$

and since from (7) the power in watts (P) is equal to the product of the amperes times the electromotive force (C E) we get

$$
\begin{equation*}
\mathrm{P}=\frac{26.8 \mathrm{w} \mathrm{E}}{\mathrm{AN}} \tag{iI}
\end{equation*}
$$

An expression for the power in watts necessary to deposit w grams of a metal whose chemical equivalent is A in N hours when an electromotive force E is used.

To illustrate the application of these formule:
The amount of oxygen liberated during the decomposition of acidulated water by a current of 2 amperes lasting 15 minutes is given by equation (8)
$\mathrm{w}=0.00001036 \times 8 \times 2 \times 900=1.492$ grams.
The amount of copper deposited in 3 hours by a current of 25 amperes from a solution of copper sulphate is found by equation (9), to be

$$
\mathrm{w}=0.0373 \times 3 \mathrm{I} .8 \times{ }_{25} \times 3=8.895 \text { grams }
$$

To determine the number of amperes that are necessary to deposit 500 grams of nickel in 5 hours, we employ formula (io) and find

$$
\mathrm{C}=\frac{26.8 \times 500}{29.35 \times 5}=91.3 \text { amperes } .
$$

The power necessary to deposit 48.8 grams of zinc
in four hours with a voltage of four is found by substituin equation (II), to be 40 watts.

$$
P=\frac{26.8 \times 48.8 \times 4}{32.7 \times 4}=40 \text { watts. }
$$

The fact that elements which form two series of salts have different electro-chemical equivalents according to the solution from which they are deposited, must be borne in mind when these calculations are made. For example copper forms two chlorides $\mathrm{Cu}_{2} \mathrm{Cl}_{2}$ and $\mathrm{CuCl}_{2}$. In the former its chemical equivalent is twice its value in the latter: hence the actual weight of copper deposited is twice as great when a solution of cuprous chloride is electrolysed as with a solution of cupric chloride; the current and time being the same.

## COUNTER-ELECTROMOTIVE FORCE,

When a molecule is formed by the combination of one or more elements, a definite amount of heat is evolved or absorbed. In most stable compounds heat is evolved: to decompose such a molecule energy must be supplied which is equivalent to this amount of heat. This energy can be supplied by an electric current. To separate metallic zinc from zinc sulphate requires energy to be given to the solution equivalent to the quantity of heat produced by the formation of zinc sulphate. Consequently when an electric current passes through an electrolyte, part of the electrical energy furnishes the energy necessary to overcome the chemical forces and only the remainder produces heat according to Joule's law. The electrolytic cell has therefore a counter-elecmotive force resisting the passage of or opposed to the current and the electromotive force producing that current.

Calling this counter-electromotive force e, the energy supplied must be a certain number of joules such that the electrical energy $=Q e=C e t ;$ depending upon the number of coulombs that have passed.
(Compare equation 6)
Or expressed in calories,

$$
\text { Electrical Energy }=\frac{1}{4 \cdot 2} \text { Cet }
$$

Now the energy of combination of various compounds may be measured by the heat which is liberated when the combination takes place, that is
Chemical Energy =wh,
when $w$ is the weight of the element in grams and $h$ is the number of calories produced when one gram of this metal combines with the other constituents of the compound.

Now from Faraday's law of electrolysis as given by equation (8) we have that w, the weight of metal deposited $=0.00001036 \mathrm{ACt}$, substituting this value for w, we have

Chemical Energy $=0.00001036$ ACth
This chemical energy must equal the electrical energy supplied to the cell available for electrolysis, that is the electrical energy not producing heat.

Therefore

$$
\frac{1}{4.2} \mathrm{Cet}=0.00001036 \mathrm{ACth}
$$

which by cancelling Ct and reducing gives

$$
\begin{equation*}
\mathrm{e}=0.0000435 \mathrm{Ah} \tag{I3}
\end{equation*}
$$

So the counter electromotive force is equal to the heat of combination of one gram in calories times the chemical equivalent times a constant, 0.0000435 .

Instead of stating the heat of combination in terms of
one gram of the metal, the more convenient method for electrolytic calculations is to state it in terms of the chemical equivalent in grams. For example, the chemical equivalent of zinc is 32.7 so that the heat of combination of 32.7 grams of zinc with other substances is the value to be used. When the values are given in terms of the molecular weight in grams these must be reduced to the heats of combination per equivalent by dividing by the valency or multiple of the valency of the element. The heat of formation of $\mathrm{Al}_{2}\left(\mathrm{SO}_{4}\right)_{3}$ is given by Thompson as 150630 calories: this means the combination of 54.2 grams of aluminium with sulphur and oxygen to give $342.3^{8}$, the molecular weight in grams of aluminium sulphate. As the equivalent of aluminium is 9.033 we must divide by 6 (twice the valency as there are two atoms) to obtain the heat per equivalent, 25315 calories.

Calling the heat per chemical equivalent in grams H and remembering that A is the chemical equivalent and $h$ is the heat evolved by the combination of one gram,

$$
\mathrm{H}=\mathrm{Ah},
$$

substituting this value in equation ( 13 ) we get

$$
\mathrm{e}=0.0000435 \mathrm{H} \text { and }
$$

since 0.0000435 equals $\frac{1}{22988}$ this equation reduces without appreciable error to the very simplest form of Thompson's law.

$$
\begin{equation*}
e=\frac{H}{23000} \tag{14}
\end{equation*}
$$

A definite case may make this deduction clearer. When 3 I .8 grams of copper, (the weight of the chemical equivalent in grams) combines to form copper sulphate, 27980 calories are developed. Now if no energy is lost as heat the electrical energy necessary to deposit 31.8
grams of copper from copper sulphate must equal this. This electrical energy is the product of e, the counterelectromotive force, and $Q$, the number of coulombs necessary to deposit 31.8 grams of copper. We find the number of coulombs by substituting in equation (8) giving

$$
\begin{gathered}
3 \mathrm{I} .8=0.00001036 \times 3 \mathrm{I} .8 \times Q \\
\text { or } Q=\frac{1}{0.00001036}=96525 \text { coulombs. }
\end{gathered}
$$

Now as one calorie equals 4.2 electrical heat units we have

$$
27980 \times 4.2=e \times 96525
$$

or $e=\frac{27980 \times 4.2}{96525}$ or practically $e=\frac{27980}{23000}=\mathbf{1 . 2 2}$
volts agreeing with formula (14) $\mathrm{e}=\frac{\mathrm{H}}{23000}$ where H is the heat produced by the combination of the chemical equivalent in grams expressed in calories.

This exceedingly simple formula* allows the electromotive force of any chemical reaction, whether it be direct as in a voltaic cell, or counter as in an electrolytic cell, to be easily calculated from the heats of combination. The calculated values agree in many cases very closely with those found by experiment. The discrepancies probably are due to the fact that all the energy of combination in the case of a voltaic cell, for instance, may not be converted into electrical energy, as some may be converted into heat which appears in the cell.

To calculate the voltage of a Daniel's cell : zinc is dissolved at one pole to form zinc sulphate, the electromotive

[^22]force is (14) $\frac{53045}{23000}=2.31$ volts : at the other pole copper is deposited which sets up a counter-motive force found in the same way to be 1.22 volts. So that the available electromotive force of the cell (neglecting the slight electromotive force where the two solutions touch) is equal to $2.3 \mathrm{I}-1.22$ or I .09 volts. The electromotive force determined experimentally is about 1.08 volts. The table at the back of the book gives some of the most important values of H to be substituted in equation 14. If other tables are used, the different methods of expressing calorific power must be considered also in some cases the heat of solution and that of any chemical combinations which take place in the cell and so give energy which aids the current. For example when copper sulphate is decomposed in an aqueous solution we have :
Cathode $\longleftrightarrow \mathrm{Cu}\left|\mathrm{SO}_{4} \leadsto \mathrm{H}_{2} \mathrm{SO}_{4} \longleftrightarrow \mathrm{H}_{2}\right| \mathrm{O} \longrightarrow$ Anode.
We have in reality two decompositions and one combination so the electrical energy to be supplied is that equivalent to the heat of combination of $\mathrm{CuSO}_{4}+$ its heat of solution in water + the heat of combination of $\mathrm{H}_{2} \mathrm{O}$ - (the heat of combination of sulphuric acid + the heat developed on diluting with water).

When the heats of combination are taken from Ostwald's tables $H$ is obtained as follows for copper sulphate and nickel sulphate

| $\mathrm{CuSO}_{4}$ | 1826 K | $\mathrm{NiSO}_{4}$ aq. | 2294 K |
| :--- | ---: | :--- | ---: |
| Heat of solution | 158 K | $\mathrm{H}_{2} \mathrm{O}$ | 684 K |
| $\mathrm{H}_{2} \mathrm{O}$ | $\frac{684 \mathrm{~K}}{2668 \mathrm{~K}}$ | $\mathrm{H}_{2} \mathrm{SO}_{4}$ aq. | $\frac{2978 \mathrm{~K}}{869}$ |
|  | $\frac{2109 \mathrm{~K}}{859}$ |  |  |

As these values are based on molecular weights in
grams to be converted to equivalent weights they must each be divided by two, since copper and nickel are divalent ions; and since $\mathrm{K}=100$ calories we get,
and

$$
\frac{279.5}{230}=1.22 \text { volts for } \mathrm{CuSO}_{4}
$$

$$
\frac{434.5}{230}=\mathrm{I} .89 \text { volts for } \mathrm{NiSO}_{4}
$$

The method of calculation just described is not in accord with the present views on the ionization of electrolytes. In order to reconcile the two, Nernst's solution tension theory must be studied. This theory, when the necessary data are at hand, leads to very similar results for the counter electromotive force and is more accurate as it takes into consideration variations in dilution.

The plan given here is retained as being of practical use on account of the great number of heats of combination which have been determined with accuracy and the simplicity of the calculation.

## OHM'S LAW FOR ELECTROLYSIS.

In a circuit where electrolytic work is being done the quantities of electricity are not related in the form of Ohm's law already given (3) as the counter-electromotive force must be considered. The total electrical energy supplied to a circuit is given by equation (6) as equal to QE or CEt.

Similarly the chemical work done is Qe or Cet.
The heat generated is, from equation (5), $\mathrm{C}^{2} \mathrm{Rt}$. Now from the principle of conservation of energy we know that the electrical energy supplied must equal the sum of the heat produced and the chemical work done.
Hence $\quad \mathrm{CEt}=\mathrm{C}^{2} \mathrm{Rt}+$ Cet
Cancelling $C$ and $t$ we obtain

$$
\begin{equation*}
E=C R+e \tag{15}
\end{equation*}
$$

Where E is the electromotive force required to produce the current C,e the counter-electromotive force of the electrolytic cell and $R$ the total ohmic resistance in the circuit.
$R$ may be separated into its constituent parts by calling Rg the resistance of the generator, Re the resistance of the conductors including any extra resistance inserted to regulate the current and Rc the resistance of the electrolytic cell : then equation ( 15 ) takes the form

$$
E=C(R g+R e+R c)+e \quad(16)
$$

and solving for $C$ we have

$$
\begin{equation*}
C=\frac{E-e}{R g+\operatorname{Re}+\mathrm{Rc}} \tag{17}
\end{equation*}
$$

The effective electromotive force in the circuit is lower than the electromotive force of the generator by the counter-electromotive force of the electrolytic cell, so the current is equal to the difference of these electromotive forces divided by the total resistance. For any value of E smaller than e , no current will flow and no metal be deposited; so this counter-electromotive force is also the value which the applied electromotive force must exceed in order to produce decomposition.

This fact permits the deposition of a single metal from solutions containing several. For instance the heat of combination per equivalent of nickel sulphate in water is 43475 calories which means that it requires $\frac{43475}{23000}=1.89$ volts to cause its decomposition and deposit nickel: to deposit copper from copper sulphate requires 1.22 volts. Therefore if we apply a voltage above 1.22 and below I .89 to a cell containing a mixture of copper and nickel sulphate in solution only copper will be deposited. Given a solution containing
silver and copper as nitrates. What are the limits of voltage to deposit silver and not copper? The heats of combination per equivalent of these salts in aqueous solution are respectively 8390 and 26205 calories, dividing by 23000 we get the counter-electromotive force as 0.365 volt for silver nitrate and I.I4 volts for copper nitrate. So any current with a voltage above 0.365 and below 1.14 will deposit only silver from this solution.

When all of the first metal is deposited the current will fall to zero unless the voltage is raised above the counter-electromotive force of the next higher metal in solution.

A convenient method of regulating the voltage is shown by the diagram.

A and B are the poles of the source of current. The circuit is closed through a conductor CD whose resistance is sufficient to cut down the current. The resistance of this conductor must of course depend on the source of current, which may be either
 primary batteries, secondary batteries, dynamo or lighting circuit. The electrolytic cell is connected so that one pole E connects with C and the other pole F connects with the movable point or slider $G$ so that any point of the conductor CD can be selected and any voltage from zero (when G is at C ) to the full voltage of the source (when $G$ is at $D$ ). By having a voltmeter V connected across the cell and starting with $G$ at $C$ the proper voltage can be applied by pushing $G$ towards $D$ until the voltmeter indicates the value desired.

The relation existing between the voltage measured
across an electrolytic cell by a voltmeter and the current passing through the cell is given by equation (i6); when Rg and Re are made zero, this becomes

$$
\begin{equation*}
E=C R c+e \tag{18}
\end{equation*}
$$

If Rc be negligible, then unless $C$ is very great $E=$ e, or the voltage across the cell is practically a constant, equal to the counter-electromotive force of the cell and independent of the current sent through it.

If either Rc or C is so great that e may be neglected then the voltage is proportional to the current flowing as in the case of simple conductor.

In most cases, however, neither can be neglected and the voltage across the cell depends not only on the counter-electromotive force but also on the resistance of, and the current flowing through the electrolytic cell. Let us consider an electrolytic cell containing a saturated solution of zinc sulphate with platinum electrodes 5 centimeters apart whose opposite submerged surfaces are 15 square centimeters, since the specific resistance is 33.7 ohms Rc in this case will be (equation (2)),

$$
33.7 \times \frac{5}{15}=11.23 \text { ohms. }
$$

The counter-electromotive force of zinc sulphate is 2.3 I volts (see tables) if the current passing is one-tenth of an ampere, the voltage across the cell will be found by equation (I8)

$$
\mathrm{E}=0.1 \times 11.23+2.3 \mathrm{I}=3.43 \text { volts. }
$$

If the current is raised to two-tenths of ampere the voltage will not be double, 6.86 , but only 4.56 volts. For

$$
E=0.2 \times 11.23+2.31=4.56 \text { volts. }
$$

If the cell were so arranged that its internal resist-
ance were only one-tenth of an ohm for small currents the voltage across its poles would be practically constant: for 0.05 of an ampere, 2.315 volts; for 0 . 10 of an ampere; 2.32 volts.

Silver nitrate in water requires only 0.365 of a volt to effect decomposition. Therefore, for such a cell, having a resistance of 100 ohms, with $1 / 4$ ampere passing through it, the voltage across the poles will be

$$
E=1 / 4 \times 100+0.365=25.365
$$

When the current is doubled this becomes

$$
\mathrm{E}=1 / 2 \times 100+0.365=50.365 .
$$

or practically double.

## EFFECT OF DISSOLVING ANODES.

In plating processes and the electrolytic refining of metals, the anode of the bath is made of the same metal as that to be deposited, so that as the current passes the anode dissolves at the same rate at which the metal is deposited on the cathode; keeping the solution at the same strength. A plating or refining bath, or any cell with a dissolving anode of the same metal as in the solution, has therefore no counter-electromotive force, since the electromotive forces of solution and decomposition are equal and opposed to each other.

Take the familiar example of a cell containing copper sulphate, the anode of platinum, the cathode of copper; this cell has a counter-electromotive force of 1.22 volts. When we substitute a copper anode for the platinum, no sulphuric acid is formed but the copper forms copper sulphate with the $\mathrm{SO}_{4}$ and the anode dissolves at the same rate as the copper is deposited. The formation of copper sulphate ordinarily generates 27,980 calories per equivalent in grams, but here the energy appears as
electricity and the electromotive force produced is exactly equal to that necessary to decompose copper sulphate. A bath or cell of this kind only introduces a certain ohmic resistance into the circuit (its e being zero) and for it formulæ $15,16,17,18$, reduce to the simplest form of Ohm's law. (3)

## CURRENT DENSITY.

The character of the deposit depends largely on the strength of current used, which can only be determined by experiment. When this has been found, the current is often described as having a certain density, that is a certain number of amperes per unit of cathode area.

In analytical work current density is expressed in amperes per 100 square centimeters of cathode area; that is area on which metal is deposited. N.D. ${ }_{100}$ is the abbreviation used: so N.D. ${ }_{100} 0.25$ means a quarter of an ampere for each ióo square centimeters of the submerged area of the cathode on which metal is deposited. As it is so important in this work to have a firm adherent deposit the current is most conveniently described by giving the voltage and current density. In some of the older books on the subject the current is given in cubic centimeters of mixed gases per minute, in order to reduce this to current density it is necessary to know that one ampere equals 10.436 c.c. of oxyhydrogen gas per minute measured at $0^{\circ} \mathrm{C}$ and 760 millimeters pressure.

## EXAMPLES,

## WITH SOLUTION OF EACH.

1. How many amperes are flowing in a circuit which in the course of one hour and 15 minutes has deposited 30.186 grams of silver? Ans. 6 amperes.

Solution. I hour and 15 minutes $=4500$ seconds : one ampere by definition deposits 0.001118 gram of silver per second. Therefore in 4500 seconds it will deposit 0.001118 $\times 4500$, or 5.03 I grams. Number of amperes flowing equals 30.186 divided by 5.03 I or 6 .
2. If a current of 15 amperes flows for one hour and 20 minutes how many coulombs will pass? How many ampere-hours will that give ?

Ans. 72000 coulombs่, 20 ampere-hours.
Solution. Substitute in equation (1)
$Q=C t=15 \times 4800=72000$ coulombs : since I hr. and 20 minutes $=4800$ seconds. 72000 coulombs $\div$ $3600=20$ ampere-hours.
3. If the specific resistance of copper is 0.000001629 , what is the resistance of a wire 200 meters long having a cross-section of 2 square millimeters?

Ans. 1.629 ohms,
Solution. Substitute in equation (2) $\mathrm{R}=\rho \frac{1}{\mathrm{a}}$
$\rho=0.000001629,1=20000$ centimeters, $\mathrm{a}=0.02$ square centimeter.

$$
\mathrm{R}=0.000001629 \frac{20000}{0.02}=1.629
$$

4. If the specific resistance of German-silver is 0.0000209 , what is the resistance of 150 meters of wire having a cross-section of 25 square millimeters.

Ans. 1.254 ohms.
Solution. Substitute in equation (2) $R=\rho \frac{1}{a}$ $\rho=0.0000209,1=15000$ centimeters, $a=0.25$ square centimeter
$\mathrm{R}=0.0000209 \frac{\mathrm{I} 5000}{0.25}=0.0000209 \times 60000=1.254$
5. What is the resistance of an electric light carbon 12 inches long by $1 / 4$ inch in diameter when its specific resistance is 0.07 . It will be sufficient to call $2 \frac{1}{2}$ centimeters one inch. Ans. 7 ohms.

Solution. Substitute in equation (2) $R=\rho \frac{1}{a}$ $\rho=0.07,1=12 \times 2.5=30$ centimeters. $a=\pi r^{2}=$ $\pi(1 / 8 \times 2.5)^{2}=0.3$ very closely. $\mathrm{R}=0.07 \frac{30}{0.3}=7 \mathrm{ohms}$ practically.
6. What is the resistance of a saturated solution of sulphate of copper placed in a tube ro c.m. long and having a cross-section of 2 square centimeters, when its specific resistance is 29.3 . Ans. 146.5 ohms.

Solution. Substitute in equation (2) $R=\rho \frac{1}{a}$
$\rho=29.3,1=10, a=2 . \quad \mathrm{R}=29.3 \frac{10}{2}=146.5$
7. What is the total resistance in a circuit composed of a voltaic cell, a copper wire, an iron wire and a piece of German-silver all connected in series when the separate resistances are respectively $3,2,4,6$ ?

Ans. 15 ohms.

Solution. Total resistance of resistances connected in series equals their sum.
8. What is the resistance of eleven incandescent lamps connected in parallel if each has a resistance of 220 ohms when hot. Ans. 20 ohms.

Solution. Resistance of equal resistance connected in parallel is equal to resistance of one divided by their number.
9. What is the resistance of four wires of respectively $20,5,4$, and 2 ohms connected in parallel.

> Ans. One ohm.

Conductance of a number of conductances connected in parallel equals their sum. $\frac{1}{20}, \frac{1}{5} \frac{1}{4}, \frac{1}{2}$ equals $.05+$ $.2+.25+.50=1$. Reciprocal of one is one.
10. If 6 amperes are flowing through 7 ohms, what is the voltage measured between the ends of this resistance? Ans. 42 volts.
Solution. Ohm's law, $\mathrm{E}=\mathrm{CR}=6 \times 7=42$.
II. If a voltage of 17 is applied to 34 ohms how many amperes will pass? Ans. 0.5 ampere.

Solution. $\quad C=\frac{E}{K}=\frac{17}{34}=0.5$
12 What is the resistance of a conductor that allows $3 / 4$ of an ampere to flow when a voltage of 75 is applied to its terminals?

Ans. 100 ohms
Solution. From Ohm's Law $R=\frac{\mathrm{E}}{\mathrm{C}}=\frac{75}{0.75}=100$
13. If a wire of 2 ohms resistance is immersed in 100 grams of distilled water how long will it take $3 / 4$ of an ampere to raise the temperature of the water from 4 to 6 degrees centigrade, assuming no loss from radiation: Ans. 12 minutes 21 seconds.

Solution. 100 grams of water raised $2^{\circ}=200$ calories. Substitute in formula (4)
$\mathrm{V}=\mathrm{C}^{2} R \mathrm{t} \times 0.24 . \mathrm{V}=200, \mathrm{C}=3 / 4, \mathrm{R}=2$.
$200=\frac{9}{16} \times 2 \times \mathrm{t} \times 0.24=0.27 \mathrm{t} . \quad \mathrm{t}=741$ seconds or 12 minutes 21 seconds.
14. How many joules would be expended as heat by 3 amperes flowing through 2 ohms for 10 minutes.

Ans. 10,800 joules.
Solution. Substitute in equation (5) $\mathrm{W}=\mathrm{C}^{2} \mathrm{Rt}$.
$\mathrm{C}=3, \mathrm{R}=2, \mathrm{t}=600 . \mathrm{W}=9 \times 2 \times 600=10800$.
15. An enclosed arc lamp requires 5 amperes to burn properly. When placed on an in 8 volt circuit, how many watts are taken? Ans. 590 watts.

Solution. Substitute in equation (7)
$\mathrm{P}=\mathrm{CE} \quad \mathrm{C}=5, \mathrm{E}=118 . \quad \mathrm{P}=5 \times 118=590$.
16. How many watts do 25 incandescent lamps take connected in parallel from a 110 volt circuit, when each lamp draws half an ampere? How many kilowatts and how many horse-power does this make? Ans. 1375 watts, 1.375 kilowatts and I. 84 horse-power.

Solution. 25 lamps at $1 / 2$ ampere apiece gives 12.5 amperes. Substitute in equation (7) $\mathrm{P}=\stackrel{\mathrm{CE}}{ } \mathrm{E}$, $\mathrm{C}=12.5, \mathrm{E}=\mathrm{I} 10, \mathrm{P}=12.5 \times 110=1375$. 1000 watts $=$ I kilowatt. 1375 watts $=1.375$ kilowatts. 746 watts $=1$ horse-power. 1375 watts $=1.84$ horsepower.
17. At full load a dynamo delivers 600 amperes at 125 volts what is its output in watts and what would be its rating in kilowatts and horse-power.

Ans. 75000 watts, 75 kilowatts, 100 horse-power.
Solution. Substitute in equation (7)

$$
\mathrm{P}=\mathrm{CE} . \quad \mathrm{C}=600, \mathrm{E}=125, \mathrm{P}=75000
$$

$\frac{75000}{1000}=75$ kilowatts, I kilowatt $=11 / 3$ horse-power, $75 \times \mathrm{I}^{1 / 3}=100$ horse-power.
18. How much zinc will be deposited from zinc sulphate by 3 amperes in 10 minutes? Ans. 0.6098 gram.

Solution. Substitute in equation (8)
$\mathrm{w}=0.00001036$ ACt. $\mathrm{A}=32.7, \mathrm{C}=3, \mathrm{t}=600$. $\mathrm{w}=0.00001036 \times 32.7 \times 3 \times 600=0.0003388 \times$ $1800=0.6098$ gram.
19. How much lead will be deposited by a current of $1 / 2$ an ampere passing for 90 minutes through lead chloride.

Ans. 2.894 grams.
Solution. Substitute in equation (8)

$$
\begin{gathered}
\mathrm{w}=0.00001036 \mathrm{ACt} \mathrm{~A}=103.5, \mathrm{C}^{1 / 2, \mathrm{t}=5400 .} \\
\mathrm{w}=0.00001036 \times 103.5 \times 1 / 2 \times 5400 \\
=0.001072 \times 2700=2.894 \text { grams. }
\end{gathered}
$$

20. How much chlorine would be liberated by $1 / 2$ an ampere passing through dilute hydrochloric acid for 13 hours.

Ans. 8.593 grams.
Solution. Substitute in equation (9)
$\mathrm{w}=0.0373 \mathrm{ACN} . \mathrm{A}=35.45, \mathrm{C}=1 / 2, \mathrm{~N}=\mathrm{I} 3$. $\mathrm{w}=0.0373 \times 35.45 \times 1 / 2 \times \mathrm{I} 3$
$=1.322 \times 6.5=8.593$ grams.
2 I How much tin will be deposited by 5 amperes flowing 6 hours through a solution of $\mathrm{SnCl}_{2}$ ?

Ans. 66.6 grams.
Solutiun. Substitute in equation (9)

$$
\begin{aligned}
& \mathrm{w}=0.0373 \mathrm{ACN} . \mathrm{A}=59.5, \mathrm{C}=5, \mathrm{~N}=6 \\
& \mathrm{w}=0.0373 \times 59.5 \times 5 \times 6 \\
& \mathrm{w}=2.220 \times 30=66.6 \text { grams. }
\end{aligned}
$$

22. How many amperes will it take to deposit $21 / 2$ pounds of copper from copper sulphate in io hours? Ans. 95.7 amperes.

Solution. Substitute in equation (io)
$\mathrm{C}=\frac{26.8 \mathrm{w}}{\mathrm{AN}} \cdot \mathrm{w}=1136$ grams. $\quad \mathrm{k}$ kilo $=2.2 \mathrm{lbs}$. hence $2.5 \mathrm{lbs}=1.136$ kilos $=1136$ grams.

$$
\mathrm{A}=3 \mathrm{1} .8, \mathrm{~N}=10 . \quad \mathrm{C}=\frac{26.8 \times 1136}{31.8 \times 10}=95.7 \text { amperes. }
$$

23. What is the minimum voltage necessary to decompose water if the heat of combination of one gram of hydrogen with oxygen is 34180 calories.

Ans. 1.486 volts.
Solution. Substitute in equation (14)

$$
e=\frac{H}{23000}=\frac{34180}{23000}=1.486 \text { volts. }
$$

24. If zinc bromide requires 1.65 volts to decompose it, what is the heat evolved by the equivalent weight of zinc in grams combining with bromine?

$$
\text { Ans. } 37950 \text { calories. }
$$

Solution. From equation (14) $\mathrm{H}=23000$ e hence $\mathrm{H}=23000 \times \mathrm{I} .65=37950$.
25. If one gram of hydrogen combining with chlorine in the presence of water evolves 39315 calories what is the voltage required for the decomposition of hydrochloric acid?

Ans. 1.71 volts.
Solution. Substitute in equation (14)

$$
\mathrm{e}=\frac{\mathrm{H}}{23000}=\frac{39315}{23000}=1.71 \text { volts. }
$$

26. It is desired to send half an ampere through ten ohms of copper sulphate. What resistance must be put in series with the cell if the current is to be drawn from a circuit whose voltage is 118 . What will be the values of this extra resistance for respectively $1 / 4$ and 2 amperes? Ans. 223.56, 457.12, and 48.39 ohms.

Solution. Neglecting the resistance of the generator and leads equation (16) becomes for this example:
$E=C\left(R_{1}+R_{c}\right)+e . E=118, C=1 / 2, R_{c}=10, e=1.22$ $118=1 / 2\left(R_{1}+10\right)+1.22$
$1 / 2 R_{1} \doteq 118-5-1.22=111.78 \quad R_{1}=223.56$ ohms.
If $C=1 / 4.118=1 / 4\left(R_{1}+10\right)+1.22$
$1 / 4 R_{1}=118-2.5-1.22=114.28 R_{1}=457.12 \mathrm{ohms}$
If $C=2.118=2\left(R_{1}+10\right)+1.22$
$2 R_{1}=118-20-1.22=96.78 . \quad R_{1}=48.39$ ohms.
27. Two batteries, having a negligible internal resistance and a voltage of two each, are to furnish current to be sent through a solution of zinc sulphate of 2.7 ohms resistance. What extra resistance must be inserted to limit the current to half an ampere? How much more must be added to cut the current down to $1 / 4$ of an ampere ?

Ans. 0.68 of an ohm, 3.38 ohms additional.
Solution. Substitute in $E=C\left(R_{1}+R_{c}\right)+e$ $\mathrm{E}=4 ., \mathrm{C}=1 / 2, R_{\mathrm{c}}=2.7, \mathrm{e}=2.3 \mathrm{I}$ (see tables) $4=1 / 2\left(R_{1}+2.7\right)+2.3 \mathrm{I} . \quad 1 / 2 R_{1}=4-1.35-2.3 \mathrm{I}$. $1 / 2 R_{1}=0.34 . \quad R_{1}=0.68$ of an ohm. If $C=1 / 4,4=1 / 4\left(R_{1}+2.7\right)+2.31 .1 / 4 R_{1}=4-0.675$ $-2.3 \mathrm{I}=1.015 . \quad \mathrm{R}_{1}=4.06 . \quad 4.06-0.68=3.38 \mathrm{ohms}$ additional.
28. What current will pass through a tube of acidulated water, having a resistance of 25 ohms, between platinum electrodes when connected to a 18 volt circuit in series with 6 lamps in parallel assuming each lamp to be 240 ohms resistance. What will be the value of the current when half the lamps are unscrewed ?

$$
\text { Ans. } 1.79 \text { and I.II amperes. }
$$

Solution. Substitute in equation ( I 7 )
$E=118, e=1.486$ example (23) $R_{g}=0$, neglected, $R_{1}=\frac{240}{6}=40, R_{c}=25$.

$$
C=\frac{118-1.486}{40+25}=\frac{116.514}{65}=1.79 \text { amperes. }
$$

For 3 lamps $R_{1}=\frac{240}{3}=80 . C=\frac{118-1.486}{80+25}=\frac{116.514}{105}$
$=1.11$ amperes
29. What is the voltage across an electrolytic cell of silver nitrate having a resistance of 40 ohms when half an ampere is passing. Ans. 20.365 volts.

Solution. Substitute in equation (18) $E=C R_{c}+e$. $C=1 / 2, R_{c}=40, e=0.365$ (see tables) $E=1 / 2 \times 40+$ $0.365=20.365$ volts.
30. What is the voltage across an electrolytic cell of zinc bromide of 2 ohms resistance when the circuit is closed by inserting $1 / 2$ ohms from a storage battery giving 4 volts. Ans. 3 volts practically.

Solution. First find C from equation ( I 7 )
$C=\frac{E-e}{R_{1}+R_{c}} . E=4, e=1.65$ (example 24) $R_{1}=1.5$
$R_{c}=2$.
$C=\frac{4-1.65}{1.5+2}=\frac{2.35}{3.5}=067$ practically
Now substitute in equation (18) $E=0.67 \times 2+1.65$ $=\mathrm{I} .34+\mathrm{I} .65=2.99$ volts, practically 3.

Thermometers.
Three scales are now in general use. These are :

1. Centigrade-C. Water freezes at $0^{\circ}$, boils at $100^{\circ}$.
2. Fahrenheit-F. " " $32^{\circ}$, " $212^{\circ}$.
3. Réaumur-R. " " $0^{\circ}$, " $80^{\circ}$.

To Convert-F. to C. $\frac{5\left(\mathrm{~F} . \mathrm{C}^{\circ}-32^{\circ}\right)}{9}=\mathrm{C} .{ }^{\circ}$
C. to F. $\frac{9 \mathrm{C} .^{\circ}}{5}+32^{\circ}=\mathrm{F} .{ }^{\circ} \quad$ Formulæ.

R to F. $\frac{9 \mathrm{R} .^{\circ}}{4}+32^{\circ}=\mathrm{F} .^{\circ}$

## TABLE SHOWING THE RELATIONS BETWEEN UNITS OF ELECTRICITY, HEAT AND POWER.

1 ampere $=1$ volt $\div 1$ ohm.
$=1$ coulomb per second.
1 ampere hour $=1$ coulomb per second kept up for one hour.
1 ampere hour $=3600$ coulombs.
1 volt $=1$ ampere $\times 1$ ohm.
1 ohm $=1$ volt $\div 1$ ampere.
1 joule $=1$ volt $\times 1$ coulomb.
$"=.2381$ calorie.
" =. 73732 foot-pound.
" $=.10194$ kilogram-meter.
1 calorie $=4.2$ joules.
" $=3.0968$ foot-pounds.
$"=.42815$ kilogram-meter.
1 foot pound $=1.3563$ joules.
" $=.32292$ calorie.
" $=.13825$ kilogram-meter
1 kilogram meter $=9.81$ joules.
" $\quad=2.3362$ calories.
$" \quad=7.233$ foot-pounds.
1 watt-hour $=1$ watt kept up for one hour.
1 watt-hour $=1$ joule per second kept up for one hour.
1 watt-hour $=3600$ joules.
" $=857.16$ calories.
" $=2654.4$ foot-pounds.
" $=366.98$ kilogram-meters
1 watt $=1$ joule per second.
$"=.2381$ calorie per second.
" $=.73732$ foot-pound per second.

1 watt $=.10194$ kilogram-meter per second.
1 watt $=.0013406$ horse-power.
$"=.001$ kilowatt.
1 horse-power $=745.94$ watts.
$" \quad=177.6$ calories per second.
1 horse-power $=10656$. calories per minute.
1 horse-power $=550$ foot pounds per second.
1 horse-power $=33000$ foot pounds per minute.

1 horse-power $=76.04$ kilogram-meters per second.
1 horse-power $=4562.4$ kilogram-meters per minute.
1 horse-power $=.74594$ kilowatts.
1 kilowatt $=1000$ watts.
" $\quad=1000$ joules per second.
" $=238.1$ calories per second.
" $=$ 14286. calories per minute
" $=$ r37.32 foot-pounds per second.
1 kilowatt $=44239$. foot-pounds per minute.
1 kilowatt $=101.94$ kilogram-meters per second.
1 kilowatt $=6116.4$ kilogram-meters per minute.
1 kilowatt $=1.3406$ horse-power.

Table of Electro-Chemical Equivalents based on the definition of the ampere and the atomic weights, oxygen being 16 , as given on page 177.

Heats of Combination in Calories, for Equivalent Weights in grams, of Chlorides, Bromides, lodides, Sulphates and Nitrates.*

| Element. | Valence. | Chloride. | Bromide. | Iodide. | Sulphate. | Nitrate. |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: |

The observed decomposition values of the acids given under hydrogen together with many of the sulphates and nitrates are taken from LeBlanc's Electro Chemistry pp. 247-8. The other observed values are from Crocker, Trans. Am. Inst. E. E. 1885 , p. 281.

The calculated values are obtained by substituting the heats of combination on page $17 \%$ in equation (14) $\mathrm{E}=\frac{\mathrm{H}}{23000}$.

[^0]:    * Schneider, J. präkt. Chem. [2], 50,46I.

[^1]:    * Dana's Mineralogy.
    $\dagger$ In these calculations the atomic weights to one decimal place are sufficient.

[^2]:    * These percentages are taken from Dana's Mineralogy.

[^3]:    * Mineralogical Magazine, 1895-97, XI, 180.

[^4]:    (*) When the magnesium sulphate is dissolved in water it is partly dissociated into Mg and $\mathrm{SO}_{4}$ ions which react with the Ba and Cl ions, so the statement " molecule of $\mathrm{SO}_{3}$ present in solution" is not literally correct but should be SO ions corresponding to molecules of $\mathrm{SO}_{8}$. This does not however affect the truth of the proportions given.

[^5]:    (*) A table of the more common N and $\mathrm{N} / 10$ solutions will be found at the back of the book.

[^6]:    * The table also gives the volume of one gram of water at different temperatures. To use these values substitute in the proportion $\mathrm{Sp} . \mathrm{Gr} . \dot{\mathrm{X}}^{\circ} \mathrm{C}: \mathrm{Sp} . \mathrm{Gr}$. $4^{\circ} \mathrm{C}:$ : vol. at $\mathrm{X}^{\circ} \mathrm{C}: 1$.

[^7]:    * Marshall, J. Society Chemical Industry vol. 18, p. 5. 1899.

[^8]:    * For a table of corrections for alcohol see Zeit. für Analytische Chemie, vol. 38, p. 253, 1899; and Morley, J. Am. Chem. Soc., vol. 26, p. I185, 1904.

[^9]:    * Ostwald Physico-chemical measurements p. 106.

[^10]:    * For details see Hempel's Gas Analysis, Dennis p. 212.

[^11]:    * This weight of 1 c.c. allows for mean humidity as well as temperature.

[^12]:    * The method given is all that is ever required but is not strictly accurate, for the true weight should be used instead of the weight in air.

[^13]:    * Calculated by Kohlrausch. Ostwald's Physico-Chemical Measurements.

[^14]:    * A very full table of heats of formation expressed in terms of K will be found in Ostwald's Outlines of General Chemistry.

[^15]:    * J. Am. Chem. Soc., Dec., 1899.
    $\dagger$ For this method of calculation, see Walker, Introduction to Physical Chemistry, p. 129.

[^16]:    * For details of these calculations see Stillman's Engineering Chemistry, p. 263.

[^17]:    * Noyes, J. Am. Chem. Soc., Vol. 17, 848.

[^18]:    * School of Mines Quarterly. January, 1895.

[^19]:    * See Tables.

[^20]:    * The latest determinations give one calorie equal to 4.2 joules which makes this constant 0.2381 .
    $\dagger$ From this point one calorie will be taken as 4.2 joules.

[^21]:    * Scientific Foundations of Analytical Chemistry p. 53.

[^22]:    * It is also applied to fused electrolytes. See Langley, J. Am. Chem. Soc., vol. 16, p. 52, 1894.

[^23]:    * United States Bureau of Standards, September, 1904.

[^24]:    * United States Bureau of Standards, September, 1904.

[^25]:    * Crooke's Select Methods, p. 693.

[^26]:    * Wied. Ann. 47.400. 1892.

[^27]:    * Smithsonian Contribution 980, p. 110, 1895.
    $\dagger$ This value is taken from Travers' Gases of the Atmosphere.

[^28]:    * Tralles.

[^29]:    * Kolb, Gerlach, Z. Anal. Chem. 8,292.

[^30]:    * Lunge and Wiernik Zeit. f. angew. Chem. 1889. 183.

[^31]:    * From the definition of the ohm.
    $\dagger$ Solution of minimum resistance.
    $\ddagger$ Saturated solution.

[^32]:    * Experiment.
